# CHAPTER 1

---

## Pymodbus Library Examples

---

*What follows is a collection of examples using the pymodbus library in various ways*

### Example Library Code

#### Asynchronous Client Example

The asynchronous client functions in the same way as the synchronous client, however, the asynchronous client uses twisted to return deferreds for the response result. Just like the synchronous version, it works against TCP, UDP, serial ASCII, and serial RTU devices.

Below an asynchronous tcp client is demonstrated running against a reference server. If you do not have a device to test with, feel free to run a pymodbus server instance or start the reference tester in the tools directory.

```
#!/usr/bin/env python
'''
Pymodbus Asynchronous Client Examples
-----
The following is an example of how to use the asynchronous modbus
client implementation from pymodbus.
'''
#-----#
# import needed libraries
#-----#
from twisted.internet import reactor, protocol
from pymodbus.constants import Defaults

#-----#
# choose the requested modbus protocol
#-----#
from pymodbus.client.async import ModbusClientProtocol
#from pymodbus.client.async import ModbusUdpClientProtocol
```

```
#-----#
# configure the client logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# helper method to test deferred callbacks
#-----#
def dassert(deferred, callback):
    def _assertor(value):
        assert value
    deferred.addCallback(lambda r: _assertor(callback(r)))
    deferred.addErrback(lambda _: _assertor(False))

#-----#
# specify slave to query
#-----#
# The slave to query is specified in an optional parameter for each
# individual request. This can be done by specifying the `unit` parameter
# which defaults to `0x00`.
#-----#
def exampleRequests(client):
    rr = client.read_coils(1, 1, unit=0x02)

#-----#
# example requests
#-----#
# simply call the methods that you would like to use. An example session
# is displayed below along with some assert checks. Note that unlike the
# synchronous version of the client, the asynchronous version returns
# deferreds which can be thought of as a handle to the callback to send
# the result of the operation. We are handling the result using the
# deferred assert helper(dassert).
#-----#
def beginAsynchronousTest(client):
    rq = client.write_coil(1, True)
    rr = client.read_coils(1,1)
    dassert(rq, lambda r: r.function_code < 0x80)           # test that we are not an error
    dassert(rr, lambda r: r.bits[0] == True)                  # test the expected value

    rq = client.write_coils(1, [True]*8)
    rr = client.read_coils(1,8)
    dassert(rq, lambda r: r.function_code < 0x80)           # test that we are not an error
    dassert(rr, lambda r: r.bits == [True]*8)                 # test the expected value

    rq = client.write_coils(1, [False]*8)
    rr = client.read_discrete_inputs(1,8)
    dassert(rq, lambda r: r.function_code < 0x80)           # test that we are not an error
    dassert(rr, lambda r: r.bits == [True]*8)                 # test the expected value

    rq = client.write_register(1, 10)
    rr = client.read_holding_registers(1,1)
    dassert(rq, lambda r: r.function_code < 0x80)           # test that we are not an error
    dassert(rr, lambda r: r.registers[0] == 10)              # test the expected value
```

```

rq = client.write_registers(1, [10]*8)
rr = client.read_input_registers(1, 8)
dassert(rq, lambda r: r.function_code < 0x80)      # test that we are not an error
dassert(rr, lambda r: r.registers == [17]*8)       # test the expected value

arguments = {
    'read_address': 1,
    'read_count': 8,
    'write_address': 1,
    'write_registers': [20]*8,
}
rq = client.readwrite_registers(**arguments)
rr = client.read_input_registers(1, 8)
dassert(rq, lambda r: r.registers == [20]*8)      # test the expected value
dassert(rr, lambda r: r.registers == [17]*8)       # test the expected value

#-----#
# close the client at some time later
#-----#
reactor.callLater(1, client.transport.loseConnection)
reactor.callLater(2, reactor.stop)

#-----#
# extra requests
#-----#
# If you are performing a request that is not available in the client
# mixin, you have to perform the request like this instead:::
#
# from pymodbus.diag_message import ClearCountersRequest
# from pymodbus.diag_message import ClearCountersResponse
#
# request = ClearCountersRequest()
# response = client.execute(request)
# if isinstance(response, ClearCountersResponse):
#     ... do something with the response
#
#-----#
#-----#
# choose the client you want
#-----#
# make sure to start an implementation to hit against. For this
# you can use an existing device, the reference implementation in the tools
# directory, or start a pymodbus server.
#-----#
defer = protocol.ClientCreator(reactor, ModbusClientProtocol
    ).connectTCP("localhost", 5020)
defer.addCallback(beginAsynchronousTest)
reactor.run()

```

## Asynchronous Server Example

```

#!/usr/bin/env python
'''
Pymodbus Asynchronous Server Example

```

```
-----  
The asynchronous server is a high performance implementation using the  
twisted library as its backend. This allows it to scale to many thousands  
of nodes which can be helpful for testing monitoring software.  
'''  
#-----#  
# import the various server implementations  
#-----#  
from pymodbus.server.async import StartTcpServer  
from pymodbus.server.async import StartUdpServer  
from pymodbus.server.async import StartSerialServer  
  
from pymodbus.device import ModbusDeviceIdentification  
from pymodbus.datastore import ModbusSequentialDataBlock  
from pymodbus.datastore import ModbusSlaveContext, ModbusServerContext  
from pymodbus.transaction import ModbusRtuFramer, ModbusAsciiFramer  
  
#-----#  
# configure the service logging  
#-----#  
import logging  
logging.basicConfig()  
log = logging.getLogger()  
log.setLevel(logging.DEBUG)  
  
#-----#  
# initialize your data store  
#-----#  
# The datastores only respond to the addresses that they are initialized to.  
# Therefore, if you initialize a DataBlock to addresses from 0x00 to 0xFF, a  
# request to 0x100 will respond with an invalid address exception. This is  
# because many devices exhibit this kind of behavior (but not all)::  
#  
#     block = ModbusSequentialDataBlock(0x00, [0]*0xff)  
#  
# Continuing, you can choose to use a sequential or a sparse DataBlock in  
# your data context. The difference is that the sequential has no gaps in  
# the data while the sparse can. Once again, there are devices that exhibit  
# both forms of behavior::  
#  
#     block = ModbusSparseDataBlock({0x00: 0, 0x05: 1})  
#     block = ModbusSequentialDataBlock(0x00, [0]*5)  
#  
# Alternately, you can use the factory methods to initialize the DataBlocks  
# or simply do not pass them to have them initialized to 0x00 on the full  
# address range::  
#  
#     store = ModbusSlaveContext(di = ModbusSequentialDataBlock.create())  
#     store = ModbusSlaveContext()  
#  
# Finally, you are allowed to use the same DataBlock reference for every  
# table or you may use a separate DataBlock for each table. This depends  
# if you would like functions to be able to access and modify the same data  
# or not::  
#  
#     block = ModbusSequentialDataBlock(0x00, [0]*0xff)  
#     store = ModbusSlaveContext(di=block, co=block, hr=block, ir=block)
```

```

#
# The server then makes use of a server context that allows the server to
# respond with different slave contexts for different unit ids. By default
# it will return the same context for every unit id supplied (broadcast
# mode). However, this can be overloaded by setting the single flag to False
# and then supplying a dictionary of unit id to context mapping:::
#
#     slaves = {
#         0x01: ModbusSlaveContext(...),
#         0x02: ModbusSlaveContext(...),
#         0x03: ModbusSlaveContext(...),
#     }
#     context = ModbusServerContext(slaves=slaves, single=False)
#
# The slave context can also be initialized in zero_mode which means that a
# request to address(0-7) will map to the address (0-7). The default is
# False which is based on section 4.4 of the specification, so address(0-7)
# will map to (1-8):::
#
#     store = ModbusSlaveContext(..., zero_mode=True)
#-----#
store = ModbusSlaveContext(
    di = ModbusSequentialDataBlock(0, [17]*100),
    co = ModbusSequentialDataBlock(0, [17]*100),
    hr = ModbusSequentialDataBlock(0, [17]*100),
    ir = ModbusSequentialDataBlock(0, [17]*100))
context = ModbusServerContext(slaves=store, single=True)

#-----#
# initialize the server information
#-----#
# If you don't set this or any fields, they are defaulted to empty strings.
#-----#
identity = ModbusDeviceIdentification()
identity.VendorName = 'Pymodbus'
identity.ProductCode = 'PM'
identity.VendorUrl = 'http://github.com/bashwork/pymodbus/'
identity.ProductName = 'Pymodbus Server'
identity.ModelName = 'Pymodbus Server'
identity.MajorMinorRevision = '1.0'

#-----#
# run the server you want
#-----#
StartTcpServer(context, identity=identity, address=("localhost", 5020))
#StartUdpServer(context, identity=identity, address=("localhost", 502))
#StartSerialServer(context, identity=identity, port='/dev/pts/3',_
#    ↪framer=ModbusRtuFramer)
#StartSerialServer(context, identity=identity, port='/dev/pts/3',_
#    ↪framer=ModbusAsciiFramer)

```

## Asynchronous Processor Example

Below is a simplified asynchronous client skeleton that was submitted by a user of the library. It can be used as a guide for implementing more complex pollers or state machines.

Feel free to test it against whatever device you currently have available. If you do not have a device to test with, feel

free to run a pymodbus server instance or start the reference tester in the tools directory.

```
#!/usr/bin/env python
'''
Pymodbus Asynchronous Processor Example
-----

The following is a full example of a continuous client processor. Feel
free to use it as a skeleton guide in implementing your own.
'''

#-----#
# import the neccessary modules
#-----#
from twisted.internet import serialport, reactor
from twisted.internet.protocol import ClientFactory
from pymodbus.factory import ClientDecoder
from pymodbus.client.async import ModbusClientProtocol

#-----#
# Choose the framer you want to use
#-----#
#from pymodbus.transaction import ModbusBinaryFramer as ModbusFramer
#from pymodbus.transaction import ModbusAsciiFramer as ModbusFramer
#from pymodbus.transaction import ModbusRtuFramer as ModbusFramer
from pymodbus.transaction import ModbusSocketFramer as ModbusFramer

#-----#
# configure the client logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger("pymodbus")
log.setLevel(logging.DEBUG)

#-----#
# state a few constants
#-----#
SERIAL_PORT  = "/dev/ttyS0"
STATUS_REGS  = (1, 2)
STATUS_COILS = (1, 3)
CLIENT_DELAY = 1

#-----#
# an example custom protocol
#-----#
# Here you can perform your main procesing loop utilizing defereds and timed
# callbacks.
#-----#
class ExampleProtocol(ModbusClientProtocol):

    def __init__(self, framer, endpoint):
        ''' Initializes our custom protocol

        :param framer: The decoder to use to process messages
        :param endpoint: The endpoint to send results to
        '''
        ModbusClientProtocol.__init__(self, framer)
        self.endpoint = endpoint
```

```

log.debug("Beginning the processing loop")
reactor.callLater(CLIENT_DELAY, self.fetch_holding_registers)

def fetch_holding_registers(self):
    ''' Defer fetching holding registers
    '''
    log.debug("Starting the next cycle")
    d = self.read_holding_registers(*STATUS_REGS)
    d.addCallbacks(self.send_holding_registers, self.error_handler)

def send_holding_registers(self, response):
    ''' Write values of holding registers, defer fetching coils

    :param response: The response to process
    '''
    self.endpoint.write(response.getRegister(0))
    self.endpoint.write(response.getRegister(1))
    d = self.read_coils(*STATUS_COILS)
    d.addCallbacks(self.start_next_cycle, self.error_handler)

def start_next_cycle(self, response):
    ''' Write values of coils, trigger next cycle

    :param response: The response to process
    '''
    self.endpoint.write(response.getBit(0))
    self.endpoint.write(response.getBit(1))
    self.endpoint.write(response.getBit(2))
    reactor.callLater(CLIENT_DELAY, self.fetch_holding_registers)

def error_handler(self, failure):
    ''' Handle any twisted errors

    :param failure: The error to handle
    '''
    log.error(failure)

#-----#
# a factory for the example protocol
#-----#
# This is used to build client protocol's if you tie into twisted's method
# of processing. It basically produces client instances of the underlying
# protocol:
#
#     Factory(Protocol) -> ProtocolInstance
#
# It also persists data between client instances (think protocol singelton).
#-----#
class ExampleFactory(ClientFactory):

    protocol = ExampleProtocol

    def __init__(self, framer, endpoint):
        ''' Remember things necessary for building a protocols '''
        self.framer = framer
        self.endpoint = endpoint

```

```
def buildProtocol(self, _):
    ''' Create a protocol and start the reading cycle '''
    proto = self.protocol(self.framer, self.endpoint)
    proto.factory = self
    return proto

#-----#
# a custom client for our device
#-----#
# Twisted provides a number of helper methods for creating and starting
# clients:
# - protocol.ClientCreator
# - reactor.connectTCP
#
# How you start your client is really up to you.
#-----#
class SerialModbusClient(serialport.SerialPort):

    def __init__(self, factory, *args, **kwargs):
        ''' Setup the client and start listening on the serial port

        :param factory: The factory to build clients with
        '''
        protocol = factory.buildProtocol(None)
        self.decoder = ClientDecoder()
        serialport.SerialPort.__init__(self, protocol, *args, **kwargs)

#-----#
# a custom endpoint for our results
#-----#
# An example line reader, this can replace with:
# - the TCP protocol
# - a context recorder
# - a database or file recorder
#-----#
class LoggingLineReader(object):

    def write(self, response):
        ''' Handle the next modbus response

        :param response: The response to process
        '''
        log.info("Read Data: %d" % response)

#-----#
# start running the processor
#-----#
# This initializes the client, the framer, the factory, and starts the
# twisted event loop (the reactor). It should be noted that a number of
# things could be chanegd as one sees fit:
# - The ModbusRtuFramer could be replaced with a ModbusAsciiFramer
# - The SerialModbusClient could be replaced with reactor.connectTCP
# - The LineReader endpoint could be replaced with a database store
#-----#
def main():
    log.debug("Initializing the client")
```

```

framer = ModbusFramer(ClientDecoder())
reader = LoggingLineReader()
factory = ExampleFactory(framer, reader)
SerialModbusClient(factory, SERIAL_PORT, reactor)
#factory = reactor.connectTCP("localhost", 502, factory)
log.debug("Starting the client")
reactor.run()

if __name__ == "__main__":
    main()

```

## Custom Message Example

```

#!/usr/bin/env python
'''
Pymodbus Synchronous Client Examples
-----

The following is an example of how to use the synchronous modbus client
implementation from pymodbus.

It should be noted that the client can also be used with
the guard construct that is available in python 2.5 and up::

    with ModbusClient('127.0.0.1') as client:
        result = client.read_coils(1,10)
        print result
    '''

import struct
#-----#
# import the various server implementations
#-----#
from pymodbus.pdu import ModbusRequest, ModbusResponse
from pymodbus.client.sync import ModbusTcpClient as ModbusClient

#-----#
# configure the client logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# create your custom message
#-----#
# The following is simply a read coil request that always reads 16 coils.
# Since the function code is already registered with the decoder factory,
# this will be decoded as a read coil response. If you implement a new
# method that is not currently implemented, you must register the request
# and response with a ClientDecoder factory.
#-----#
class CustomModbusRequest(ModbusRequest):

    function_code = 1

```

```

def __init__(self, address):
    ModbusRequest.__init__(self)
    self.address = address
    self.count = 16

def encode(self):
    return struct.pack('>HH', self.address, self.count)

def decode(self, data):
    self.address, self.count = struct.unpack('>HH', data)

def execute(self, context):
    if not (1 <= self.count <= 0x7d0):
        return self.doException(merror.IllegalValue)
    if not context.validate(self.function_code, self.address, self.count):
        return self.doException(merror.IllegalAddress)
    values = context.getValues(self.function_code, self.address, self.count)
    return CustomModbusResponse(values)

#-----#
# This could also have been defined as
#-----#
from pymodbus.bit_read_message import ReadCoilsRequest

class Read16CoilsRequest(ReadCoilsRequest):

    def __init__(self, address):
        ''' Initializes a new instance

        :param address: The address to start reading from
        '''
        ReadCoilsRequest.__init__(self, address, 16)

#-----#
# execute the request with your client
#-----#
# using the with context, the client will automatically be connected
# and closed when it leaves the current scope.
#-----#
with ModbusClient('127.0.0.1') as client:
    request = CustomModbusRequest(0)
    result = client.execute(request)
    print result

```

## Custom Datablock Example

```

#!/usr/bin/env python
'''
Pymodbus Server With Custom Datablock Side Effect
-----

This is an example of performing custom logic after a value has been
written to the datastore.
'''
```

```

#-----#
# import the modbus libraries we need
#-----#
from __future__ import print_function
from pymodbus.server.async import StartTcpServer
from pymodbus.device import ModbusDeviceIdentification
from pymodbus.datastore import ModbusSparseDataBlock
from pymodbus.datastore import ModbusSlaveContext, ModbusServerContext

# initialize the server information
#-----#

identity = ModbusDeviceIdentification()
identity.VendorName = 'pymodbus'
identity.ProductCode = 'PM'

```

```
identity.VendorUrl      = 'http://github.com/bashwork/pymodbus/'
identity.ProductName    = 'pymodbus Server'
identity.ModelName      = 'pymodbus Server'
identity.MajorMinorRevision = '1.0'

#-----#
# run the server you want
#-----#

# p = Process(target=device_writer, args=(queue,))
# p.start()
StartTcpServer(context, identity=identity, address=("localhost", 5020))
```

## Modbus Logging Example

```
#!/usr/bin/env python
'''

Pymodbus Logging Examples
-----

'''

import logging
import logging.handlers as Handlers

#-----#
# This will simply send everything logged to console
#-----#
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# This will send the error messages in the specified namespace to a file.
# The available namespaces in pymodbus are as follows:
#-----#
# * pymodbus.*          - The root namespace
# * pymodbus.server.*   - all logging messages involving the modbus server
# * pymodbus.client.*   - all logging messages involving the client
# * pymodbus.protocol.* - all logging messages inside the protocol layer
#-----#
logging.basicConfig()
log = logging.getLogger('pymodbus.server')
log.setLevel(logging.ERROR)

#-----#
# This will send the error messages to the specified handlers:
# * docs.python.org/library/logging.html
#-----#
log = logging.getLogger('pymodbus')
log.setLevel(logging.ERROR)
handlers = [
    Handlers.RotatingFileHandler("logfile", maxBytes=1024*1024),
    Handlers.SMTPHandler("mx.host.com", "pymodbus@host.com", ["support@host.com"],
    ↵"Pymodbus"),
    Handlers.SysLogHandler(facility="daemon"),
    Handlers.DatagramHandler('localhost', 12345),
]
```

```
[log.addHandler(h) for h in handlers]
```

## Modbus Payload Building/Decoding Example

```
#!/usr/bin/env python
'''
Pymodbus Payload Building/Decoding Example
-----

# Run modbus-payload-server.py or synchronous-server.py to check the behavior
'''

from pymodbus.constants import Endian
from pymodbus.payload import BinaryPayloadDecoder
from pymodbus.payload import BinaryPayloadBuilder
from pymodbus.client.sync import ModbusTcpClient as ModbusClient
from pymodbus.compat import iteritems

#-----#
# configure the client logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.INFO)

#-----#
# We are going to use a simple client to send our requests
#-----#
client = ModbusClient('127.0.0.1', port=5020)
client.connect()

#-----#
# If you need to build a complex message to send, you can use the payload
# builder to simplify the packing logic.
#
# Here we demonstrate packing a random payload layout, unpacked it looks
# like the following:
#
# - a 8 byte string 'abcdefgh'
# - a 32 bit float 22.34
# - a 16 bit unsigned int 0x1234
# - another 16 bit unsigned int 0x5678
# - an 8 bit int 0x12
# - an 8 bit bitstring [0,1,0,1,1,0,1,0]
#-----#
builder = BinaryPayloadBuilder(endian=Endian.Big)
builder.add_string('abcdefgh')
builder.add_32bit_float(22.34)
builder.add_16bit_uint(0x1234)
builder.add_16bit_uint(0x5678)
builder.add_8bit_int(0x12)
builder.add_bits([0,1,0,1,1,0,1,0])
payload = builder.build()
address = 0
result = client.write_registers(address, payload, skip_encode=True, unit=1)
```

```
#-----#
# If you need to decode a collection of registers in a weird layout, the
# payload decoder can help you as well.
#
# Here we demonstrate decoding a random register layout, unpacked it looks
# like the following:
#
# - a 8 byte string 'abcdefgh'
# - a 32 bit float 22.34
# - a 16 bit unsigned int 0x1234
# - another 16 bit unsigned int which we will ignore
# - an 8 bit int 0x12
# - an 8 bit bitstring [0,1,0,1,1,0,1,0]
#-----#
address = 0x00
count = 8
result = client.read_holding_registers(address, count, unit=1)
decoder = BinaryPayloadDecoder.fromRegisters(result.registers, endian=Endian.Big)
decoded = {
    'string': decoder.decode_string(8),
    'float': decoder.decode_32bit_float(),
    '16uint': decoder.decode_16bit_uint(),
    'ignored': decoder.skip_bytes(2),
    '8int': decoder.decode_8bit_int(),
    'bits': decoder.decode_bits(),
}

print("-" * 60)
print("Decoded Data")
print("-" * 60)
for name, value in iteritems(decoded):
    print ("%s\t" % name, value)

#-----#
# close the client
#-----#
client.close()
```

## Modbus Payload Server Context Building Example

```
#!/usr/bin/env python
'''
Pymodbus Server Payload Example
-----

If you want to initialize a server context with a complicated memory
layout, you can actually use the payload builder.
'''

#-----#
# import the various server implementations
#-----#
from pymodbus.server.sync import StartTcpServer

from pymodbus.device import ModbusDeviceIdentification
from pymodbus.datastore import ModbusSequentialDataBlock
from pymodbus.datastore import ModbusSlaveContext, ModbusServerContext
```

```

#-----#
# import the payload builder
#-----#

from pymodbus.constants import Endian
from pymodbus.payload import BinaryPayloadDecoder
from pymodbus.payload import BinaryPayloadBuilder

#-----#
# configure the service logging
#-----#

import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# build your payload
#-----#

builder = BinaryPayloadBuilder(endian=Endian.Little)
# builder.add_string('abcdefgh')
# builder.add_32bit_float(22.34)
# builder.add_16bit_uint(4660)
# builder.add_8bit_int(18)
builder.add_bits([0,1,0,1,1,0,1,0])

#-----#
# use that payload in the data store
#-----#

# Here we use the same reference block for each underlying store.
#-----#

block = ModbusSequentialDataBlock(1, builder.to_registers())
store = ModbusSlaveContext(di = block, co = block, hr = block, ir = block)
context = ModbusServerContext(slaves=store, single=True)

#-----#
# initialize the server information
#-----#

# If you don't set this or any fields, they are defaulted to empty strings.
#-----#

identity = ModbusDeviceIdentification()
identity.VendorName = 'Pymodbus'
identity.ProductCode = 'PM'
identity.VendorUrl = 'http://github.com/bashwork/pymodbus/'
identity.ProductName = 'Pymodbus Server'
identity.ModelName = 'Pymodbus Server'
identity.MajorMinorRevision = '1.0'

#-----#
# run the server you want
#-----#

StartTcpServer(context, identity=identity, address=("localhost", 5020))

```

## Synchronous Client Example

It should be noted that each request will block waiting for the result. If asynchronous behaviour is required, please use the asynchronous client implementations. The synchronous client, works against TCP, UDP, serial ASCII, and serial RTU devices.

The synchronous client exposes the most popular methods of the modbus protocol, however, if you want to execute other methods against the device, simple create a request instance and pass it to the execute method.

Below an synchronous tcp client is demonstrated running against a reference server. If you do not have a device to test with, feel free to run a pymodbus server instance or start the reference tester in the tools directory.

```
#!/usr/bin/env python
'''
Pymodbus Synchronous Client Examples
-----

The following is an example of how to use the synchronous modbus client
implementation from pymodbus.

It should be noted that the client can also be used with
the guard construct that is available in python 2.5 and up::

    with ModbusClient('127.0.0.1') as client:
        result = client.read_coils(1,10)
        print result
    '''

#-----#
# import the various server implementations
#-----#
from pymodbus.client.sync import ModbusTcpClient as ModbusClient
#from pymodbus.client.sync import ModbusUdpClient as ModbusClient
#from pymodbus.client.sync import ModbusSerialClient as ModbusClient

#-----#
# configure the client logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# choose the client you want
#-----#
# make sure to start an implementation to hit against. For this
# you can use an existing device, the reference implementation in the tools
# directory, or start a pymodbus server.
#
# If you use the UDP or TCP clients, you can override the framer being used
# to use a custom implementation (say RTU over TCP). By default they use the
# socket framer:::
#
#     client = ModbusClient('localhost', port=5020, framer=ModbusRtuFramer)
#
# It should be noted that you can supply an ipv4 or an ipv6 host address for
# both the UDP and TCP clients.
#
# There are also other options that can be set on the client that controls
```

```

# how transactions are performed. The current ones are:
#
# * retries - Specify how many retries to allow per transaction (default = 3)
# * retry_on_empty - Is an empty response a retry (default = False)
# * source_address - Specifies the TCP source address to bind to
#
# Here is an example of using these options::
#
#     client = ModbusClient('localhost', retries=3, retry_on_empty=True)
#-----
client = ModbusClient('localhost', port=5020)
#client = ModbusClient(method='ascii', port='/dev/pts/2', timeout=1)
# client = ModbusClient(method='rtu', port='/dev/ttyp0', timeout=1)
client.connect()

#-----
# specify slave to query
#-----
# The slave to query is specified in an optional parameter for each
# individual request. This can be done by specifying the `unit` parameter
# which defaults to `0x00`
#-----
log.debug("Reading Coils")
rr = client.read_coils(1, 1, unit=0x01)

#-----
# example requests
#-----
# simply call the methods that you would like to use. An example session
# is displayed below along with some assert checks. Note that some modbus
# implementations differentiate holding/input discrete/coils and as such
# you will not be able to write to these, therefore the starting values
# are not known to these tests. Furthermore, some use the same memory
# blocks for the two sets, so a change to one is a change to the other.
# Keep both of these cases in mind when testing as the following will
# _only_ pass with the supplied async modbus server (script supplied).
#-----
log.debug("Write to a Coil and read back")

## Synchronous Server Example

```

#!/usr/bin/env python
'''
```

*Pymodbus Synchronous Server Example*

---

The synchronous server is implemented in pure python without any third party libraries (unless you need to use the serial protocols which require pyserial). This is helpful in constrained or old environments where using twisted just is not feasable. What follows is an example of its use:

```
'''  
#-----#  
# import the various server implementations  
#-----#  
from pymodbus.server.sync import StartTcpServer  
from pymodbus.server.sync import StartUdpServer  
from pymodbus.server.sync import StartSerialServer  
  
from pymodbus.device import ModbusDeviceIdentification  
from pymodbus.datastore import ModbusSequentialDataBlock  
from pymodbus.datastore import ModbusSlaveContext, ModbusServerContext  
  
from pymodbus.transaction import ModbusRtuFramer  
#-----#  
# configure the service logging  
#-----#  
import logging  
logging.basicConfig()  
log = logging.getLogger()  
log.setLevel(logging.DEBUG)  
  
#-----#  
# initialize your data store  
#-----#  
# The datastores only respond to the addresses that they are initialized to.  
# Therefore, if you initialize a DataBlock to addresses of 0x00 to 0xFF, a  
# request to 0x100 will respond with an invalid address exception. This is  
# because many devices exhibit this kind of behavior (but not all)::  
#  
#     block = ModbusSequentialDataBlock(0x00, [0]*0xff)  
#  
# Continuing, you can choose to use a sequential or a sparse DataBlock in  
# your data context. The difference is that the sequential has no gaps in  
# the data while the sparse can. Once again, there are devices that exhibit  
# both forms of behavior::  
#  
#     block = ModbusSparseDataBlock({0x00: 0, 0x05: 1})  
#     block = ModbusSequentialDataBlock(0x00, [0]*5)  
#  
# Alternately, you can use the factory methods to initialize the DataBlocks  
# or simply do not pass them to have them initialized to 0x00 on the full  
# address range::  
#  
#     store = ModbusSlaveContext(di = ModbusSequentialDataBlock.create())  
#     store = ModbusSlaveContext()  
#  
# Finally, you are allowed to use the same DataBlock reference for every  
# table or you may use a separate DataBlock for each table. This depends  
# if you would like functions to be able to access and modify the same data  
# or not::  
#
```

```

#     block = ModbusSequentialDataBlock(0x00, [0]*0xff)
#     store = ModbusSlaveContext(di=block, co=block, hr=block)
#
# The server then makes use of a server context that allows the server to
# respond with different slave contexts for different unit ids. By default
# it will return the same context for every unit id supplied (broadcast
# mode). However, this can be overloaded by setting the single flag to False
# and then supplying a dictionary of unit id to context mapping:::
#
#     slaves = {
#         0x01: ModbusSlaveContext(...),
#         0x02: ModbusSlaveContext(...),
#         0x03: ModbusSlaveContext(...),
#     }
#     context = ModbusServerContext(slaves=slaves, single=False)
#
# The slave context can also be initialized in zero_mode which means that a
# request to address(0-7) will map to the address (0-7). The default is
# False which is based on section 4.4 of the specification, so address(0-7)
# will map to (1-8):::
#
#     store = ModbusSlaveContext(..., zero_mode=True)
#-----#
store = ModbusSlaveContext(
    di = ModbusSequentialDataBlock(0, [17]*100),
    co = ModbusSequentialDataBlock(0, [17]*100),
    hr = ModbusSequentialDataBlock(0, [17]*100),
    ir = ModbusSequentialDataBlock(0, [17]*100))
context = ModbusServerContext(slaves=store, single=True)

#-----#
# initialize the server information
#-----#
# If you don't set this or any fields, they are defaulted to empty strings.
#-----#
identity = ModbusDeviceIdentification()
identity.VendorName = 'Pymodbus'
identity.ProductCode = 'PM'
identity.VendorUrl = 'http://github.com/riptideio/pymodbus/'
identity.ProductName = 'Pymodbus Server'
identity.ModelName = 'Pymodbus Server'
identity.MajorMinorRevision = '1.0'

#-----#
# run the server you want
#-----#
# Tcp:
StartTcpServer(context, identity=identity, address=("localhost", 5020))

# Udp:
#StartUdpServer(context, identity=identity, address=("localhost", 502))

# Ascii:
#StartSerialServer(context, identity=identity, port='/dev/pts/3', timeout=1)

# RTU:
# StartSerialServer(context, framer=ModbusRtuFramer, identity=identity, port='/dev/
→ptyp0', timeout=.005, baudrate=9600)

```

## Synchronous Client Performance Check

Below is a quick example of how to test the performance of a tcp modbus device using the synchronous tcp client. If you do not have a device to test with, feel free to run a pymodbus server instance or start the reference tester in the tools directory.

```
#!/usr/bin/env python
'''
Pymodbus Performance Example
-----

The following is an quick performance check of the synchronous
modbus client.

'''

#-----#
# import the necessary modules
#-----#
from __future__ import print_function
import logging, os
from time import time
from multiprocessing import log_to_stderr
# from pymodbus.client.sync import ModbusTcpClient
from pymodbus.client.sync import ModbusSerialClient

#-----#
# choose between threads or processes
#-----#
#from multiprocessing import Process as Worker
from threading import Thread as Worker
from threading import Lock
_thread_lock = Lock()

#-----#
# initialize the test
#-----#
# Modify the parameters below to control how we are testing the client:
#
# * workers - the number of workers to use at once
# * cycles - the total number of requests to send
# * host - the host to send the requests to
#-----#
workers = 10
cycles = 1000
host = '127.0.0.1'

#-----#
# perform the test
#-----#
# This test is written such that it can be used by many threads of processes
# although it should be noted that there are performance penalties
# associated with each strategy.
#-----#
def single_client_test(host, cycles):

## Changing Default Framers

```

#!/usr/bin/env python
'''
Pymodbus Client Framer Overload
-----

All of the modbus clients are designed to have pluggable framers
so that the transport and protocol are decoupled. This allows a user
to define or plug in their custom protocols into existing transports
(like a binary framer over a serial connection).

It should be noted that although you are not limited to trying whatever
you would like, the library makes no guarantees that all framers with
all transports will produce predictable or correct results (for example
tcp transport with an RTU framer). However, please let us know of any
success cases that are not documented!
'''

#-----
# import the modbus client and the framers
#-----#

```

```
from pymodbus.client.sync import ModbusTcpClient as ModbusClient

#-----#
# Import the modbus framer that you want
#-----#
#-----#
#from pymodbus.transaction import ModbusSocketFramer as ModbusFramer
from pymodbus.transaction import ModbusRtuFramer as ModbusFramer
#from pymodbus.transaction import ModbusBinaryFramer as ModbusFramer
#from pymodbus.transaction import ModbusAsciiFramer as ModbusFramer

#-----#
# configure the client logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# Initialize the client
#-----#
client = ModbusClient('localhost', port=5020, framer=ModbusFramer)
client.connect()

#-----#
# perform your requests
#-----#
rq = client.write_coil(1, True)
rr = client.read_coils(1,1)
assert(rq.function_code < 0x80)      # test that we are not an error
assert(rr.bits[0] == True)           # test the expected value

#-----#
# close the client
#-----#
client.close()
```

## Thread Safe Datastore Example

## Modbus Message Generator Example

This is an example of a utility that will build examples of modbus messages in all the available formats in the pymodbus package.

### Program Source

```

#!/usr/bin/env python
'''
Modbus Message Generator
-----

The following is an example of how to generate example encoded messages
for the supplied modbus format:

* tcp   - `./generate-messages.py -f tcp -m rx -b`
* ascii - `./generate-messages.py -f ascii -m tx -a`
* rtu   - `./generate-messages.py -f rtu -m rx -b`
* binary - `./generate-messages.py -f binary -m tx -b`

## Example Response Messages

```
# -----
# What follows is a collection of encoded messages that can
# be used to test the message-parser. Simply uncomment the
# messages you want decoded and run the message parser with
# the given arguments. What follows is the listing of messages
# that are encoded in each format:
#
# - ReadHoldingRegistersResponse
# - ReadDiscreteInputsResponse
# - ReadInputRegistersResponse
# - ReadCoilsResponse
# - WriteMultipleCoilsResponse
# - WriteMultipleRegistersResponse
# - WriteSingleRegisterResponse
# - WriteSingleCoilResponse
# - ReadWriteMultipleRegistersResponse
# - ReadExceptionStatusResponse
# - GetCommEventCounterResponse
# - GetCommEventLogResponse
# - ReportSlaveIdResponse
# - ReadFileRecordResponse
# - WriteFileRecordResponse
# - MaskWriteRegisterResponse
# - ReadFifoQueueResponse
# - ReadDeviceInformationResponse
# - ReturnQueryDataResponse
# - RestartCommunicationsOptionResponse
# - ReturnDiagnosticRegisterResponse
# - ChangeAsciiInputDelimiterResponse
# - ForceListenOnlyModeResponse
# - ClearCountersResponse
# - ReturnBusMessageCountResponse
# - ReturnBusCommunicationErrorCountResponse
# - ReturnBusExceptionErrorCountResponse
# - ReturnSlaveMessageCountResponse
# - ReturnSlaveNoReponseCountResponse
# - ReturnSlaveNAKCountResponse
# - ReturnSlaveBusyCountResponse
# - ReturnSlaveBusCharacterOverrunCountResponse
# - ReturnIopOverrunCountResponse
# - ClearOverrunCountResponse
# - GetClearModbusPlusResponse

## Modbus Message Parsing Example

This is an example of a parser to decode raw messages to a readable description. It will attempt to decode a message to the request and response version of a message if possible. Here is an example output:

```
$ ./message-parser.py -b -m 000112340006ff076d
=====
Decoding Message 000112340006ff076d
=====
ServerDecoder
-----
name      = ReadExceptionStatusRequest
check     = 0x0
unit_id   = 0xff
transaction_id = 0x1
protocol_id = 0x1234
documentation =
    This function code is used to read the contents of eight Exception Status
    outputs in a remote device. The function provides a simple method for
    accessing this information, because the Exception Output references are
    known (no output reference is needed in the function).

ClientDecoder
-----
name      = ReadExceptionStatusResponse
check     = 0x0
status    = 0x6d
unit_id   = 0xff
transaction_id = 0x1
protocol_id = 0x1234
documentation =
    The normal response contains the status of the eight Exception Status
    outputs. The outputs are packed into one data byte, with one bit
    per output. The status of the lowest output reference is contained
    in the least significant bit of the byte. The contents of the eight
    Exception Status outputs are device specific.
```

## Program Source

```
#!/usr/bin/env python
'''
Modbus Message Parser

## Example Messages

See the documentation for the message generator for a collection of messages that can be parsed by this utility.

## Synchronous Serial Forwarder

```
#!/usr/bin/env python
'''
Pymodbus Synchronous Serial Forwarder
-----

We basically set the context for the tcp serial server to be that of a
serial client! This is just an example of how clever you can be with
the data context (basically anything can become a modbus device).
'''

#-----#
# import the various server implementations
#-----#
from pymodbus.server.sync import StartTcpServer as StartServer
from pymodbus.client.sync import ModbusSerialClient as ModbusClient

from pymodbus.datastore.remote import RemoteSlaveContext
from pymodbus.datastore import ModbusSlaveContext, ModbusServerContext

#-----#
# configure the service logging
#-----#
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----#
# initialize the datastore(serial client)
#-----#
client = ModbusClient(method='ascii', port='/dev/pts/14')
store = RemoteSlaveContext(client)
context = ModbusServerContext(slaves=store, single=True)

#-----#
# run the server you want
#-----#
StartServer(context)
```

## Modbus Scraper Example

```
#!/usr/bin/env python
'''

This is a simple scraper that can be pointed at a
modbus device to pull down all its values and store
them as a collection of sequential data blocks.
'''

import pickle
from optparse import OptionParser
from twisted.internet import serialport, reactor
from twisted.internet.protocol import ClientFactory
from pymodbus.datastore import ModbusSequentialDataBlock
from pymodbus.datastore import ModbusSlaveContext
from pymodbus.factory import ClientDecoder
from pymodbus.client.async import ModbusClientProtocol
```

## Libmodbus Client Facade

```
#!/usr/bin/env python
'''
Libmodbus Protocol Wrapper
-----

What follows is an example wrapper of the libmodbus library
(http://libmodbus.org/documentation/) for use with pymodbus.
There are two utilities involved here:

* LibmodbusLevel1Client

This is simply a python wrapper around the c library. It is
mostly a clone of the pylibmodbus implementation, but I plan
on extending it to implement all the available protocol using
the raw execute methods.

* LibmodbusClient

This is just another modbus client that can be used just like
any other client in pymodbus.

For these to work, you must have `cffi` and `libmodbus-dev` installed:

    sudo apt-get install libmodbus-dev
    pip install cffi
'''

#-----#
# import system libraries

## Remote Single Server Context

'''

*Although there is a remote server context already in the main library, it works under the assumption that users would have a server context of the following form:::*

```
server_context = {
    0x00: client('host1.something.com'),
    0x01: client('host2.something.com'),
    0x02: client('host3.something.com')
}
```

*This example is how to create a server context where the client is pointing to the same host, but the requested slave id is used as the slave for the client:::*

```
server_context = {
    0x00: client('host1.something.com', 0x00),
    0x01: client('host1.something.com', 0x01),
    0x02: client('host1.something.com', 0x02)
}
'''

## Example Frontend Code

### Glade/GTK Frontend Example

#### Main Program

This is an example simulator that is written using the pygtk bindings. Although it currently does not have a frontend for modifying the context values, it does allow one to expose N virtual modbus devices to a network which is useful for testing data center monitoring tools.

---

**Note:** The virtual networking code will only work on linux

---

```
#!/usr/bin/env python
#-----#
# System
#-----#
import os
import getpass
import pickle
from threading import Thread

#-----#
# For Gui
#-----#
from twisted.internet import gtk2reactor
gtk2reactor.install()
```

```

import gtk
from gtk import glade

#-----
# SNMP Simulator
#-----
from twisted.internet import reactor
from twisted.internet import error as twisted_error
from pymodbus.server.async import ModbusServerFactory
from pymodbus.datastore import ModbusServerContext,ModbusSlaveContext

#-----

## Bottle Web Frontend Example

### Summary

This is a simple example of adding a live REST api on top of a running pymodbus server. This uses the bottle microframework to achieve this.

The example can be hosted under twisted as well as the bottle internal server and can furthermore be run behind gunicorn, cherrypi, etc wsgi containers.

### Main Program

```

'''
Pymodbus Web Frontend
=====

This is a simple web frontend using bottle as the web framework.
This can be hosted using any wsgi adapter.
'''

from __future__ import print_function
import json, inspect
from bottle import route, request, Bottle
from bottle import static_file
from bottle import jinja2_template as template

#-----
# configure the client logging
#-----
import logging
logging.basicConfig()
log = logging.getLogger()
log.setLevel(logging.DEBUG)

#-----

```

```
# REST API
#-----#
class Response(object):
    """
    A collection of common responses for the frontend api
    """

    success = { 'status' : 200 }
    failure = { 'status' : 500 }

class ModbusApiWebApp(object):
    """
    This is the web REST api interface into the pymodbus
    service. It can be consumed by any utility that can
    make web requests (javascript).
    """

    _namespace = '/api/v1'

    def __init__(self, server):

## Pymodbus Library API Documentation

---

*The following are the API documentation strings taken from the sourcecode*

### **bit\_read\_message — Bit Read Modbus Messages**

#### **API Documentation**

##### **Bit Reading Request/Response messages**

```
class pymodbus.bit_read_message.ReadBitsRequestBase(address, count, **kwargs)
```

Base class for Messages Requesting bit values

```
__init__(address, count, **kwargs)
```

Initializes the read request data

##### **Parameters**

- **address** – The start address to read from
- **count** – The number of bits after ‘address’ to read

```
__str__()
```

Returns a string representation of the instance

**Returns** A string representation of the instance

```
decode(data)
```

Decodes a request pdu

**Parameters** **data** – The packet data to decode

```
encode()
```

Encodes a request pdu

**Returns** The encoded pdu

```
get_response_pdu_size()
    Func_code (1 byte) + Byte Count(1 byte) + Quantity of Coils (n Bytes)/8, if the remainder is different of
    0 then N = N+1 :return:

class pymodbus.bit_read_message.ReadBitsResponseBase (values, **kwargs)
    Base class for Messages responding to bit-reading values

    __init__ (values, **kwargs)
        Initializes a new instance

        Parameters values – The requested values to be returned

    __str__ ()
        Returns a string representation of the instance

        Returns A string representation of the instance

    decode (data)
        Decodes response pdu

        Parameters data – The packet data to decode

    encode ()
        Encodes response pdu

        Returns The encoded packet message

    getBit (address)
        Helper function to get the specified bit's value

        Parameters address – The bit to query

        Returns The value of the requested bit

    resetBit (address)
        Helper function to set the specified bit to 0

        Parameters address – The bit to reset

    setBit (address, value=1)
        Helper function to set the specified bit

        Parameters
            • address – The bit to set
            • value – The value to set the bit to

class pymodbus.bit_read_message.ReadCoilsRequest (address=None, count=None, **kwargs)
    This function code is used to read from 1 to 2000(0x7d0) contiguous status of coils in a remote device. The Request PDU specifies the starting address, ie the address of the first coil specified, and the number of coils. In the PDU Coils are addressed starting at zero. Therefore coils numbered 1-16 are addressed as 0-15.

    __init__ (address=None, count=None, **kwargs)
        Initializes a new instance

        Parameters
            • address – The address to start reading from
            • count – The number of bits to read

    execute (context)
        Run a read coils request against a datastore
```

Before running the request, we make sure that the request is in the max valid range (0x001-0x7d0). Next we make sure that the request is valid against the current datastore.

**Parameters** **context** – The datastore to request from

**Returns** The initializes response message, exception message otherwise

```
class pymodbus.bit_read_message.ReadCoilsResponse (values=None, **kwargs)
```

The coils in the response message are packed as one coil per bit of the data field. Status is indicated as 1= ON and 0= OFF. The LSB of the first data byte contains the output addressed in the query. The other coils follow toward the high order end of this byte, and from low order to high order in subsequent bytes.

If the returned output quantity is not a multiple of eight, the remaining bits in the final data byte will be padded with zeros (toward the high order end of the byte). The Byte Count field specifies the quantity of complete bytes of data.

```
__init__ (values=None, **kwargs)
```

Initializes a new instance

**Parameters** **values** – The request values to respond with

```
class pymodbus.bit_read_message.ReadDiscreteInputsRequest (address=None,
```

```
count=None, **kwargs)
```

This function code is used to read from 1 to 2000(0x7d0) contiguous status of discrete inputs in a remote device. The Request PDU specifies the starting address, ie the address of the first input specified, and the number of inputs. In the PDU Discrete Inputs are addressed starting at zero. Therefore Discrete inputs numbered 1-16 are addressed as 0-15.

```
__init__ (address=None, count=None, **kwargs)
```

Initializes a new instance

**Parameters**

- **address** – The address to start reading from
- **count** – The number of bits to read

```
execute (context)
```

Run a read discrete input request against a datastore

Before running the request, we make sure that the request is in the max valid range (0x001-0x7d0). Next we make sure that the request is valid against the current datastore.

**Parameters** **context** – The datastore to request from

**Returns** The initializes response message, exception message otherwise

```
class pymodbus.bit_read_message.ReadDiscreteInputsResponse (values=None, **kwargs)
```

The discrete inputs in the response message are packed as one input per bit of the data field. Status is indicated as 1= ON; 0= OFF. The LSB of the first data byte contains the input addressed in the query. The other inputs follow toward the high order end of this byte, and from low order to high order in subsequent bytes.

If the returned input quantity is not a multiple of eight, the remaining bits in the final data byte will be padded with zeros (toward the high order end of the byte). The Byte Count field specifies the quantity of complete bytes of data.

```
__init__ (values=None, **kwargs)
```

Initializes a new instance

**Parameters** **values** – The request values to respond with

## bit\_write\_message — Bit Write Modbus Messages

### API Documentation

#### Bit Writing Request/Response

TODO write mask request/response

```
class pymodbus.bit_write_message.WriteSingleCoilRequest(address=None, value=None, **kwargs)
```

This function code is used to write a single output to either ON or OFF in a remote device.

The requested ON/OFF state is specified by a constant in the request data field. A value of FF 00 hex requests the output to be ON. A value of 00 00 requests it to be OFF. All other values are illegal and will not affect the output.

The Request PDU specifies the address of the coil to be forced. Coils are addressed starting at zero. Therefore coil numbered 1 is addressed as 0. The requested ON/OFF state is specified by a constant in the Coil Value field. A value of 0XFF00 requests the coil to be ON. A value of 0X0000 requests the coil to be off. All other values are illegal and will not affect the coil.

```
__init__(address=None, value=None, **kwargs)
```

Initializes a new instance

#### Parameters

- **address** – The variable address to write
- **value** – The value to write at address

```
__str__()
```

Returns a string representation of the instance

**Returns** A string representation of the instance

```
decode(data)
```

Decodes a write coil request

**Parameters** **data** – The packet data to decode

```
encode()
```

Encodes write coil request

**Returns** The byte encoded message

```
execute(context)
```

Run a write coil request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** The populated response or exception message

```
get_response_pdu_size()
```

Func\_code (1 byte) + Output Address (2 byte) + Output Value (2 Bytes) :return:

```
class pymodbus.bit_write_message.WriteSingleCoilResponse(address=None, value=None, **kwargs)
```

The normal response is an echo of the request, returned after the coil state has been written.

```
__init__(address=None, value=None, **kwargs)
```

Initializes a new instance

#### Parameters

- **address** – The variable address written to
- **value** – The value written at address

**\_\_str\_\_()**

Returns a string representation of the instance

**Returns** A string representation of the instance

**decode(data)**

Decodes a write coil response

**Parameters** **data** – The packet data to decode

**encode()**

Encodes write coil response

**Returns** The byte encoded message

```
class pymodbus.bit_write_message.WriteMultipleCoilsRequest(address=None,          val-
                                                             ues=None, **kwargs)
```

"This function code is used to force each coil in a sequence of coils to either ON or OFF in a remote device. The Request PDU specifies the coil references to be forced. Coils are addressed starting at zero. Therefore coil numbered 1 is addressed as 0.

The requested ON/OFF states are specified by contents of the request data field. A logical ‘1’ in a bit position of the field requests the corresponding output to be ON. A logical ‘0’ requests it to be OFF."

**\_\_init\_\_(address=None, values=None, \*\*kwargs)**

Initializes a new instance

**Parameters**

- **address** – The starting request address
- **values** – The values to write

**\_\_str\_\_()**

Returns a string representation of the instance

**Returns** A string representation of the instance

**decode(data)**

Decodes a write coils request

**Parameters** **data** – The packet data to decode

**encode()**

Encodes write coils request

**Returns** The byte encoded message

**execute(context)**

Run a write coils request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** The populated response or exception message

```
class pymodbus.bit_write_message.WriteMultipleCoilsResponse(address=None,
                                                               count=None,
                                                               **kwargs)
```

The normal response returns the function code, starting address, and quantity of coils forced.

**\_\_init\_\_(address=None, count=None, \*\*kwargs)**

Initializes a new instance

### Parameters

- **address** – The starting variable address written to
- **count** – The number of values written

`__str__()`

Returns a string representation of the instance

**Returns** A string representation of the instance

`decode(data)`

Decodes a write coils response

**Parameters** `data` – The packet data to decode

`encode()`

Encodes write coils response

**Returns** The byte encoded message

## client.common — Twisted Async Modbus Client

### API Documentation

#### Modbus Client Common

This is a common client mixin that can be used by both the synchronous and asynchronous clients to simplify the interface.

`class pymodbus.client.common.ModbusClientMixin`

This is a modbus client mixin that provides additional factory methods for all the current modbus methods. This can be used instead of the normal pattern of:

```
# instead of this
client = ModbusClient(....)
request = ReadCoilsRequest(1, 10)
response = client.execute(request)

# now like this
client = ModbusClient(....)
response = client.read_coils(1, 10)
```

`mask_write_register(*args, **kwargs)`

### Parameters

- **address** – The address of the register to write
- **and\_mask** – The and bitmask to apply to the register address
- **or\_mask** – The or bitmask to apply to the register address
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

`read_coils(address, count=1, **kwargs)`

### Parameters

- **address** – The starting address to read from

- **count** – The number of coils to read
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**read\_discrete\_inputs** (address, count=1, \*\*kwargs)

**Parameters**

- **address** – The starting address to read from
- **count** – The number of discretes to read
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**read\_holding\_registers** (address, count=1, \*\*kwargs)

**Parameters**

- **address** – The starting address to read from
- **count** – The number of registers to read
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**read\_input\_registers** (address, count=1, \*\*kwargs)

**Parameters**

- **address** – The starting address to read from
- **count** – The number of registers to read
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**readwrite\_registers** (\*args, \*\*kwargs)

**Parameters**

- **read\_address** – The address to start reading from
- **read\_count** – The number of registers to read from address
- **write\_address** – The address to start writing to
- **write\_registers** – The registers to write to the specified address
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**write\_coil** (address, value, \*\*kwargs)

**Parameters**

- **address** – The starting address to write to
- **value** – The value to write to the specified address
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**write\_coils** (address, values, \*\*kwargs)

### Parameters

- **address** – The starting address to write to
- **values** – The values to write to the specified address
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**write\_register**(*address*, *value*, \*\**kwargs*)

### Parameters

- **address** – The starting address to write to
- **value** – The value to write to the specified address
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

**write\_registers**(*address*, *values*, \*\**kwargs*)

### Parameters

- **address** – The starting address to write to
- **values** – The values to write to the specified address
- **unit** – The slave unit this request is targeting

**Returns** A deferred response handle

## client.sync — Twisted Synchronous Modbus Client

### API Documentation

**class** pymodbus.client.sync.**BaseModbusClient**(*framer*, \*\**kwargs*)

Interface for a modbus synchronous client. Defined here are all the methods for performing the related request methods. Derived classes simply need to implement the transport methods and set the correct framer.

**\_\_enter\_\_()**

Implement the client with enter block

**Returns** The current instance of the client

**\_\_exit\_\_(*klass*, *value*, *traceback*)**

Implement the client with exit block

**\_\_init\_\_(*framer*, \*\**kwargs*)**

Initialize a client instance

**Parameters** **framer** – The modbus framer implementation to use

**\_\_str\_\_()**

Builds a string representation of the connection

**Returns** The string representation

**\_recv(*size*)**

Reads data from the underlying descriptor

**Parameters** **size** – The number of bytes to read

**Returns** The bytes read

**\_send (request)**  
Sends data on the underlying socket

**Parameters** **request** – The encoded request to send

**Returns** The number of bytes written

**close ()**  
Closes the underlying socket connection

**connect ()**  
Connect to the modbus remote host

**Returns** True if connection succeeded, False otherwise

**execute (request=None)**

**Parameters** **request** – The request to process

**Returns** The result of the request execution

```
class pymodbus.client.sync.ModbusTcpClient(host='127.0.0.1', port=502, framer=<class 'pymodbus.transaction.ModbusSocketFramer'>, **kwargs)
```

Implementation of a modbus tcp client

```
__init__(host='127.0.0.1', port=502, framer=<class 'pymodbus.transaction.ModbusSocketFramer'>, **kwargs)
```

Initialize a client instance

**Parameters**

- **host** – The host to connect to (default 127.0.0.1)
- **port** – The modbus port to connect to (default 502)
- **source\_address** – The source address tuple to bind to (default ('', 0))
- **timeout** – The timeout to use for this socket (default Defaults.Timeout)
- **framer** – The modbus framer to use (default ModbusSocketFramer)

---

**Note:** The host argument will accept ipv4 and ipv6 hosts

---

**\_\_str\_\_ ()**  
Builds a string representation of the connection

**Returns** The string representation

**\_recv (size)**  
Reads data from the underlying descriptor

**Parameters** **size** – The number of bytes to read

**Returns** The bytes read

**\_send (request)**  
Sends data on the underlying socket

**Parameters** **request** – The encoded request to send

**Returns** The number of bytes written

```
close()
    Closes the underlying socket connection

connect()
    Connect to the modbus tcp server

    Returns True if connection succeeded, False otherwise

class pymodbus.client.sync.ModbusUdpClient (host=‘127.0.0.1’, port=502, framer=<class
                                                ‘pymodbus.transaction.ModbusSocketFramer’>,
                                                **kwargs)
    Implementation of a modbus udp client

    _init_(host=‘127.0.0.1’, port=502, framer=<class ‘pymodbus.transaction.ModbusSocketFramer’>,
            **kwargs)
        Initialize a client instance

        Parameters
            • host – The host to connect to (default 127.0.0.1)
            • port – The modbus port to connect to (default 502)
            • framer – The modbus framer to use (default ModbusSocketFramer)
            • timeout – The timeout to use for this socket (default None)

    _str_()
        Builds a string representation of the connection

        Returns The string representation

classmethod _get_address_family(address)
    A helper method to get the correct address family for a given address.

    Parameters address – The address to get the af for

    Returns AF_INET for ipv4 and AF_INET6 for ipv6

    _recv(size)
        Reads data from the underlying descriptor

        Parameters size – The number of bytes to read

        Returns The bytes read

    _send(request)
        Sends data on the underlying socket

        Parameters request – The encoded request to send

        Returns The number of bytes written

    close()
        Closes the underlying socket connection

    connect()
        Connect to the modbus tcp server

        Returns True if connection succeeded, False otherwise

class pymodbus.client.sync.ModbusSerialClient (method=‘ascii’, **kwargs)
    Implementation of a modbus serial client

    static _ModbusSerialClient__implementation(method)
        Returns the requested framer
```

**Method** The serial framer to instantiate

**Returns** The requested serial framer

**\_\_init\_\_(method='ascii', \*\*kwargs)**

Initialize a serial client instance

The methods to connect are:

- ascii
- rtu
- binary

### Parameters

- **method** – The method to use for connection
- **port** – The serial port to attach to
- **stopbits** – The number of stop bits to use
- **bytesize** – The bytesize of the serial messages
- **parity** – Which kind of parity to use
- **baudrate** – The baud rate to use for the serial device
- **timeout** – The timeout between serial requests (default 3s)

**\_\_str\_\_()**

Builds a string representation of the connection

**Returns** The string representation

**\_recv(size)**

Reads data from the underlying descriptor

**Parameters** **size** – The number of bytes to read

**Returns** The bytes read

**\_send(request)**

Sends data on the underlying socket

If receive buffer still holds some data then flush it.

Sleep if last send finished less than 3.5 character times ago.

**Parameters** **request** – The encoded request to send

**Returns** The number of bytes written

**close()**

Closes the underlying socket connection

**connect()**

Connect to the modbus serial server

**Returns** True if connection succeeded, False otherwise

## client.async — Twisted Async Modbus Client

### API Documentation

#### Implementation of a Modbus Client Using Twisted

Example run:

```
from twisted.internet import reactor, protocol
from pymodbus.client.async import ModbusClientProtocol

def printResult(result):
    print "Result: %d" % result.bits[0]

def process(client):
    result = client.write_coil(1, True)
    result.addCallback(printResult)
    reactor.callLater(1, reactor.stop)

defer = protocol.ClientCreator(reactor, ModbusClientProtocol
    ).connectTCP("localhost", 502)
defer.addCallback(process)
```

Another example:

```
from twisted.internet import reactor
from pymodbus.client.async import ModbusClientFactory

def process():
    factory = reactor.connectTCP("localhost", 502, ModbusClientFactory())
    reactor.stop()

if __name__ == "__main__":
    reactor.callLater(1, process)
    reactor.run()
```

**class** pymodbus.client.async.**ModbusClientProtocol** (*framer=None, \*\*kwargs*)

This represents the base modbus client protocol. All the application layer code is deferred to a higher level wrapper.

**\_\_init\_\_** (*framer=None, \*\*kwargs*)

Initializes the framer module

**Parameters** **framer** – The framer to use for the protocol

**\_buildResponse** (*tid*)

Helper method to return a deferred response for the current request.

**Parameters** **tid** – The transaction identifier for this response

**Returns** A defer linked to the latest request

**\_handleResponse** (*reply*)

Handle the processed response and link to correct deferred

**Parameters** **reply** – The reply to process

**connectionLost** (*reason*)

Called upon a client disconnect

**Parameters** `reason` – The reason for the disconnect

**connectionMade()**  
Called upon a successful client connection.

**dataReceived(data)**  
Get response, check for valid message, decode result

**Parameters** `data` – The data returned from the server

**execute(request)**  
Starts the producer to send the next request to consumer.write(Frame(request))

**class** `pymodbus.client.async.ModbusClientFactory`  
Simple client protocol factory

**protocol**  
alias of `ModbusClientProtocol`

## constants — Modbus Default Values

### API Documentation

#### Constants For Modbus Server/Client

This is the single location for storing default values for the servers and clients.

**class** `pymodbus.constants.Defaults`

A collection of modbus default values

##### **Port**

The default modbus tcp server port (502)

##### **Retries**

The default number of times a client should retry the given request before failing (3)

##### **RetryOnEmpty**

A flag indicating if a transaction should be retried in the case that an empty response is received. This is useful for slow clients that may need more time to process a request.

##### **Timeout**

The default amount of time a client should wait for a request to be processed (3 seconds)

##### **Reconnects**

The default number of times a client should attempt to reconnect before deciding the server is down (0)

##### **TransactionId**

The starting transaction identifier number (0)

##### **ProtocolId**

The modbus protocol id. Currently this is set to 0 in all but proprietary implementations.

##### **UnitId**

The modbus slave address. Currently this is set to 0x00 which means this request should be broadcast to all the slave devices (really means that all the devices should respond).

##### **Baudrate**

The speed at which the data is transmitted over the serial line. This defaults to 19200.

**Parity**

The type of checksum to use to verify data integrity. This can be one of the following:

- |                                  |
|----------------------------------|
| - (E) even - 1 0 1 0   P(0)      |
| - (O) odd - 1 0 1 0   P(1)       |
| - (N) none - 1 0 1 0   no parity |

This defaults to (N)none.

**Bytesize**

The number of bits in a byte of serial data. This can be one of 5, 6, 7, or 8. This defaults to 8.

**Stopbits**

The number of bits sent after each character in a message to indicate the end of the byte. This defaults to 1.

**ZeroMode**

Indicates if the slave datastore should use indexing at 0 or 1. More about this can be read in section 4.4 of the modbus specification.

**IgnoreMissingSlaves**

In case a request is made to a missing slave, this defines if an error should be returned or simply ignored. This is useful for the case of a serial server emulator where a request to a non-existent slave on a bus will never respond. The client in this case will simply timeout.

**class pymodbus.constants.ModbusStatus**

These represent various status codes in the modbus protocol.

**Waiting**

This indicates that a modbus device is currently waiting for a given request to finish some running task.

**Ready**

This indicates that a modbus device is currently free to perform the next request task.

**On**

This indicates that the given modbus entity is on

**Off**

This indicates that the given modbus entity is off

**SlaveOn**

This indicates that the given modbus slave is running

**SlaveOff**

This indicates that the given modbus slave is not running

**class pymodbus.constantsEndian**

An enumeration representing the various byte endianess.

**Auto**

This indicates that the byte order is chosen by the current native environment.

**Big**

This indicates that the bytes are in little endian format

**Little**

This indicates that the bytes are in big endian format

---

**Note:** I am simply borrowing the format strings from the python struct module for my convenience.

---

```
class pymodbus.constants.ModbusPlusOperation
    Represents the type of modbus plus request

    GetStatistics
        Operation requesting that the current modbus plus statistics be returned in the response.

    ClearStatistics
        Operation requesting that the current modbus plus statistics be cleared and not returned in the response.

class pymodbus.constants.DeviceInformation
    Represents what type of device information to read

    Basic
        This is the basic (required) device information to be returned. This includes VendorName, ProductCode, and MajorMinorRevision code.

    Regular
        In addition to basic data objects, the device provides additional and optional identification and description data objects. All of the objects of this category are defined in the standard but their implementation is optional.

    Extended
        In addition to regular data objects, the device provides additional and optional identification and description private data about the physical device itself. All of these data are device dependent.

    Specific
        Request to return a single data object.

class pymodbus.constants.MoreData
    Represents the more follows condition

    Nothing
        This indicates that no more objects are going to be returned.

    KeepReading
        This indicates that there are more objects to be returned.
```

## Server Datastores and Contexts

*The following are the API documentation strings taken from the sourcecode*

### store — Datastore for Modbus Server Context

#### API Documentation

#### Modbus Server Datastore

For each server, you will create a ModbusServerContext and pass in the default address space for each data access. The class will create and manage the data.

Further modification of said data accesses should be performed with [get,set][access]Values(address, count)

#### Datastore Implementation

There are two ways that the server datastore can be implemented. The first is a complete range from ‘address’ start to ‘count’ number of indecies. This can be thought of as a straight array:

```
data = range(1, 1 + count)
[1,2,3,...,count]
```

The other way that the datastore can be implemented (and how many devices implement it) is a associate-array:

```
data = {1:'1', 3:'3', ..., count:'count'}
[1,3,...,count]
```

The difference between the two is that the latter will allow arbitrary gaps in its datastore while the former will not. This is seen quite commonly in some modbus implementations. What follows is a clear example from the field:

Say a company makes two devices to monitor power usage on a rack. One works with three-phase and the other with a single phase. The company will dictate a modbus data mapping such that registers:

```
n:      phase 1 power
n+1:    phase 2 power
n+2:    phase 3 power
```

Using this, layout, the first device will implement n, n+1, and n+2, however, the second device may set the latter two values to 0 or will simply not implemented the registers thus causing a single read or a range read to fail.

I have both methods implemented, and leave it up to the user to change based on their preference.

**class pymodbus.datastore.store.`BaseModbusDataBlock`**

Base class for a modbus datastore

**Derived classes must create the following fields:** @address The starting address point @defult\_value The default value of the datastore @values The actual datastore values

**Derived classes must implemented the following methods:** validate(self, address, count=1) getValues(self, address, count=1) setValues(self, address, values)

**`__iter__()`**

Iterater over the data block data

**Returns** An iterator of the data block data

**`__str__()`**

Build a representation of the datastore

**Returns** A string representation of the datastore

**`default(count, value=False)`**

Used to initialize a store to one value

**Parameters**

- **count** – The number of fields to set
- **value** – The default value to set to the fields

**`getValues(address, count=1)`**

Returns the requested values from the datastore

**Parameters**

- **address** – The starting address
- **count** – The number of values to retrieve

**Returns** The requested values from a:a+c

**`reset()`**

Resets the datastore to the initialized default value

**setValues** (*address, values*)

Returns the requested values from the datastore

**Parameters**

- **address** – The starting address
- **values** – The values to store

**validate** (*address, count=1*)

Checks to see if the request is in range

**Parameters**

- **address** – The starting address
- **count** – The number of values to test for

**Returns** True if the request is within range, False otherwise

**class** pymodbus.datastore.store.**ModbusSequentialDataBlock** (*address, values*)

Creates a sequential modbus datastore

**\_\_init\_\_** (*address, values*)

Initializes the datastore

**Parameters**

- **address** – The starting address of the datastore
- **values** – Either a list or a dictionary of values

**classmethod create** (*klass*)

Factory method to create a datastore with the full address space initialized to 0x00

**Returns** An initialized datastore

**getValues** (*address, count=1*)

Returns the requested values of the datastore

**Parameters**

- **address** – The starting address
- **count** – The number of values to retrieve

**Returns** The requested values from a:a+c

**setValues** (*address, values*)

Sets the requested values of the datastore

**Parameters**

- **address** – The starting address
- **values** – The new values to be set

**validate** (*address, count=1*)

Checks to see if the request is in range

**Parameters**

- **address** – The starting address
- **count** – The number of values to test for

**Returns** True if the request is within range, False otherwise

```
class pymodbus.datastore.store.ModbusSparseDataBlock (values)
    Creates a sparse modbus datastore

    __init__ (values)
        Initializes the datastore

        Using the input values we create the default datastore value and the starting address

        Parameters values – Either a list or a dictionary of values

    classmethod create (klass)
        Factory method to create a datastore with the full address space initialized to 0x00

        Returns An initialized datastore

    getValues (address, count=1)
        Returns the requested values of the datastore

        Parameters
            • address – The starting address
            • count – The number of values to retrieve

        Returns The requested values from a:a+c

    setValues (address, values)
        Sets the requested values of the datastore

        Parameters
            • address – The starting address
            • values – The new values to be set

    validate (address, count=1)
        Checks to see if the request is in range

        Parameters
            • address – The starting address
            • count – The number of values to test for

        Returns True if the request is within range, False otherwise
```

## context — Modbus Server Contexts

### API Documentation

```
class pymodbus.datastore.context.ModbusSlaveContext (*args, **kwargs)
    This creates a modbus data model with each data access stored in its own personal block

    __init__ (*args, **kwargs)
        Initializes the datastores, defaults to fully populated sequential data blocks if none are passed in.

        Parameters kwargs – Each element is a ModbusDataBlock
            ‘di’ - Discrete Inputs initializer ‘co’ - Coils initializer ‘hr’ - Holding Register initializer ‘ir’ -
            Input Registers initializer

    __str__ ()
        Returns a string representation of the context

        Returns A string representation of the context
```

**getValues** (*fx, address, count=1*)  
Validates the request to make sure it is in range

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address
- **count** – The number of values to retrieve

**Returns** The requested values from a:a+c

**reset** ()  
Resets all the datastores to their default values

**setValues** (*fx, address, values*)  
Sets the datastore with the supplied values

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address
- **values** – The new values to be set

**validate** (*fx, address, count=1*)  
Validates the request to make sure it is in range

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address
- **count** – The number of values to test

**Returns** True if the request is within range, False otherwise

**class** pymodbus.datastore.context.**ModbusServerContext** (*slaves=None, single=True*)  
This represents a master collection of slave contexts. If single is set to true, it will be treated as a single context so every unit-id returns the same context. If single is set to false, it will be interpreted as a collection of slave contexts.

**\_\_contains\_\_** (*slave*)  
Check if the given slave is in this list

**Parameters** **slave** – slave The slave to check for existence

**Returns** True if the slave exists, False otherwise

**\_\_delitem\_\_** (*slave*)  
Wrapper used to access the slave context

**Parameters** **slave** – The slave context to remove

**\_\_getitem\_\_** (*slave*)  
Used to get access to a slave context

**Parameters** **slave** – The slave context to get

**Returns** The requested slave context

**\_\_init\_\_** (*slaves=None, single=True*)  
Initializes a new instance of a modbus server context.

**Parameters**

- **slaves** – A dictionary of client contexts
- **single** – Set to true to treat this as a single context

**\_\_iter\_\_()**

Iterates over the current collection of slave contexts.

**Returns** An iterator over the slave contexts

**\_\_setitem\_\_(slave, context)**

Used to set a new slave context

**Parameters**

- **slave** – The slave context to set
- **context** – The new context to set for this slave

## remote — Remote Slave Context

### API Documentation

**class pymodbus.datastore.remote.RemoteSlaveContext (client)**

TODO This creates a modbus data model that connects to a remote device (depending on the client used)

**\_\_RemoteSlaveContext\_\_build\_mapping()**

A quick helper method to build the function code mapper.

**\_\_RemoteSlaveContext\_\_extract\_result(fx, result)**

A helper method to extract the values out of a response. TODO make this consistent (values?)

**\_\_init\_\_(client)**

Initializes the datastores

**Parameters** **client** – The client to retrieve values with

**\_\_str\_\_()**

Returns a string representation of the context

**Returns** A string representation of the context

**getValues(fx, address, count=1)**

Validates the request to make sure it is in range

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address
- **count** – The number of values to retrieve

**Returns** The requested values from a:a+c

**reset()**

Resets all the datastores to their default values

**setValues(fx, address, values)**

Sets the datastore with the supplied values

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address

- **values** – The new values to be set

**validate** (*fx, address, count=1*)  
Validates the request to make sure it is in range

#### Parameters

- **fx** – The function we are working with
- **address** – The starting address
- **count** – The number of values to test

**Returns** True if the request is within range, False otherwise

## diag\_message — Diagnostic Modbus Messages

### API Documentation

#### Diagnostic Record Read/Write

These need to be tied into a the current server context or linked to the appropriate data

**class** pymodbus.diag\_message.**DiagnosticStatusRequest** (\*\*kwargs)  
This is a base class for all of the diagnostic request functions

**\_\_init\_\_** (\*\*kwargs)  
Base initializer for a diagnostic request  
**decode** (*data*)  
Base decoder for a diagnostic request

**Parameters** **data** – The data to decode into the function code

**encode** ()  
Base encoder for a diagnostic response we encode the data set in self.message  
**Returns** The encoded packet

**get\_response\_pdu\_size** ()  
Func\_code (1 byte) + Sub function code (2 byte) + Data (2 \* N bytes) :return:

**class** pymodbus.diag\_message.**DiagnosticStatusResponse** (\*\*kwargs)  
This is a base class for all of the diagnostic response functions

It works by performing all of the encoding and decoding of variable data and lets the higher classes define what extra data to append and how to execute a request

**\_\_init\_\_** (\*\*kwargs)  
Base initializer for a diagnostic response  
**decode** (*data*)  
Base decoder for a diagnostic response

**Parameters** **data** – The data to decode into the function code

**encode** ()  
Base encoder for a diagnostic response we encode the data set in self.message  
**Returns** The encoded packet

```
class pymodbus.diag_message.DiagnosticStatusSimpleRequest (data=0, **kwargs)
A large majority of the diagnostic functions are simple status request functions. They work by sending 0x0000 as data and their function code and they are returned 2 bytes of data.
```

If a function inherits this, they only need to implement the execute method

```
__init__ (data=0, **kwargs)
General initializer for a simple diagnostic request
```

The data defaults to 0x0000 if not provided as over half of the functions require it.

**Parameters** **data** – The data to send along with the request

```
execute (*args)
Base function to raise if not implemented
```

```
class pymodbus.diag_message.DiagnosticStatusSimpleResponse (data=0, **kwargs)
A large majority of the diagnostic functions are simple status request functions. They work by sending 0x0000 as data and their function code and they are returned 2 bytes of data.
```

```
__init__ (data=0, **kwargs)
General initializer for a simple diagnostic response
```

**Parameters** **data** – The resulting data to return to the client

```
class pymodbus.diag_message.ReturnQueryDataRequest (message=0, **kwargs)
The data passed in the request data field is to be returned (looped back) in the response. The entire response message should be identical to the request.
```

```
__init__ (message=0, **kwargs)
Initializes a new instance of the request
```

**Parameters** **message** – The message to send to loopback

```
execute (*args)
Executes the loopback request (builds the response)
```

**Returns** The populated loopback response message

```
class pymodbus.diag_message.ReturnQueryDataResponse (message=0, **kwargs)
The data passed in the request data field is to be returned (looped back) in the response. The entire response message should be identical to the request.
```

```
__init__ (message=0, **kwargs)
Initializes a new instance of the response
```

**Parameters** **message** – The message to loopback

```
class pymodbus.diag_message.RestartCommunicationsOptionRequest (toggle=False,
**kwargs)
```

The remote device serial line port must be initialized and restarted, and all of its communications event counters are cleared. If the port is currently in Listen Only Mode, no response is returned. This function is the only one that brings the port out of Listen Only Mode. If the port is not currently in Listen Only Mode, a normal response is returned. This occurs before the restart is executed.

```
__init__ (toggle=False, **kwargs)
Initializes a new request
```

**Parameters** **toggle** – Set to True to toggle, False otherwise

```
execute (*args)
Clear event log and restart
```

**Returns** The initialized response message

```
class pymodbus.diag_message.R restartCommunicationsOptionResponse (toggle=False,  
                                                               **kwargs)
```

The remote device serial line port must be initialized and restarted, and all of its communications event counters are cleared. If the port is currently in Listen Only Mode, no response is returned. This function is the only one that brings the port out of Listen Only Mode. If the port is not currently in Listen Only Mode, a normal response is returned. This occurs before the restart is executed.

```
__init__ (toggle=False, **kwargs)
```

Initializes a new response

**Parameters** `toggle` – Set to True if we toggled, False otherwise

```
class pymodbus.diag_message.R returnDiagnosticRegisterRequest (data=0, **kwargs)
```

The contents of the remote device's 16-bit diagnostic register are returned in the response

```
execute (*args)
```

Execute the diagnostic request on the given device

**Returns** The initialized response message

```
class pymodbus.diag_message.R returnDiagnosticRegisterResponse (data=0, **kwargs)
```

The contents of the remote device's 16-bit diagnostic register are returned in the response

```
class pymodbus.diag_message.R changeAsciiInputDelimiterRequest (data=0, **kwargs)
```

The character 'CHAR' passed in the request data field becomes the end of message delimiter for future messages (replacing the default LF character). This function is useful in cases of a Line Feed is not required at the end of ASCII messages.

```
execute (*args)
```

Execute the diagnostic request on the given device

**Returns** The initialized response message

```
class pymodbus.diag_message.R changeAsciiInputDelimiterResponse (data=0, **kwargs)
```

The character 'CHAR' passed in the request data field becomes the end of message delimiter for future messages (replacing the default LF character). This function is useful in cases of a Line Feed is not required at the end of ASCII messages.

```
class pymodbus.diag_message.R forceListenOnlyModeRequest (data=0, **kwargs)
```

Forces the addressed remote device to its Listen Only Mode for MODBUS communications. This isolates it from the other devices on the network, allowing them to continue communicating without interruption from the addressed remote device. No response is returned.

```
execute (*args)
```

Execute the diagnostic request on the given device

**Returns** The initialized response message

```
class pymodbus.diag_message.R forceListenOnlyModeResponse (**kwargs)
```

Forces the addressed remote device to its Listen Only Mode for MODBUS communications. This isolates it from the other devices on the network, allowing them to continue communicating without interruption from the addressed remote device. No response is returned.

This does not send a response

```
__init__ (**kwargs)
```

Initializer to block a return response

```
class pymodbus.diag_message.R clearCountersRequest (data=0, **kwargs)
```

The goal is to clear all counters and the diagnostic register. Also, counters are cleared upon power-up

```
execute (*args)
```

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ClearCountersResponse (data=0, **kwargs)`

The goal is to clear all counters and the diagnostic register. Also, counters are cleared upon power-up

**class** `pymodbus.diag_message.ReturnBusMessageCountRequest (data=0, **kwargs)`

The response data field returns the quantity of messages that the remote device has detected on the communications systems since its last restart, clear counters operation, or power-up

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ReturnBusMessageCountResponse (data=0, **kwargs)`

The response data field returns the quantity of messages that the remote device has detected on the communications systems since its last restart, clear counters operation, or power-up

**class** `pymodbus.diag_message.ReturnBusCommunicationErrorCountRequest (data=0,`

`**kwargs)`

The response data field returns the quantity of CRC errors encountered by the remote device since its last restart, clear counter operation, or power-up

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ReturnBusCommunicationErrorCountResponse (data=0,`

`**kwargs)`

The response data field returns the quantity of CRC errors encountered by the remote device since its last restart, clear counter operation, or power-up

**class** `pymodbus.diag_message.ReturnBusExceptionErrorCountRequest (data=0,`

`**kwargs)`

The response data field returns the quantity of modbus exception responses returned by the remote device since its last restart, clear counters operation, or power-up

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ReturnBusExceptionErrorCountResponse (data=0,`

`**kwargs)`

The response data field returns the quantity of modbus exception responses returned by the remote device since its last restart, clear counters operation, or power-up

**class** `pymodbus.diag_message.ReturnSlaveMessageCountRequest (data=0, **kwargs)`

The response data field returns the quantity of messages addressed to the remote device, or broadcast, that the remote device has processed since its last restart, clear counters operation, or power-up

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ReturnSlaveMessageCountResponse (data=0, **kwargs)`

The response data field returns the quantity of messages addressed to the remote device, or broadcast, that the remote device has processed since its last restart, clear counters operation, or power-up

**class** `pymodbus.diag_message.ReturnSlaveNoResponseCountRequest (data=0, **kwargs)`

The response data field returns the quantity of messages addressed to the remote device, or broadcast, that the remote device has processed since its last restart, clear counters operation, or power-up

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class pymodbus.diag\_message.ReturnSlaveNoResponseCountResponse (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device, or broadcast, that the remote device has processed since its last restart, clear counters operation, or power-up

**class pymodbus.diag\_message.ReturnSlaveNAKCountRequest (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device for which it returned a Negative Acknowledge (NAK) exception response, since its last restart, clear counters operation, or power-up. Exception responses are described and listed in section 7 .

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class pymodbus.diag\_message.ReturnSlaveNAKCountResponse (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device for which it returned a Negative Acknowledge (NAK) exception response, since its last restart, clear counters operation, or power-up. Exception responses are described and listed in section 7.

**class pymodbus.diag\_message.ReturnSlaveBusyCountRequest (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device for which it returned a Slave Device Busy exception response, since its last restart, clear counters operation, or power-up.

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class pymodbus.diag\_message.ReturnSlaveBusyCountResponse (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device for which it returned a Slave Device Busy exception response, since its last restart, clear counters operation, or power-up.

**class pymodbus.diag\_message.ReturnSlaveBusCharacterOverrunCountRequest (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device that it could not handle due to a character overrun condition, since its last restart, clear counters operation, or power-up. A character overrun is caused by data characters arriving at the port faster than they can be stored, or by the loss of a character due to a hardware malfunction.

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class pymodbus.diag\_message.ReturnSlaveBusCharacterOverrunCountResponse (data=0, \*\*kwargs)**

The response data field returns the quantity of messages addressed to the remote device that it could not handle due to a character overrun condition, since its last restart, clear counters operation, or power-up. A character overrun is caused by data characters arriving at the port faster than they can be stored, or by the loss of a character due to a hardware malfunction.

**class pymodbus.diag\_message.ReturnIopOverrunCountRequest (data=0, \*\*kwargs)**

An IOP overrun is caused by data characters arriving at the port faster than they can be stored, or by the loss of a character due to a hardware malfunction. This function is specific to the 884.

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ReturnIopOverrunCountResponse (data=0, **kwargs)`

The response data field returns the quantity of messages addressed to the slave that it could not handle due to an 884 IOP overrun condition, since its last restart, clear counters operation, or power-up.

**class** `pymodbus.diag_message.ClearOverrunCountRequest (data=0, **kwargs)`

Clears the overrun error counter and reset the error flag

An error flag should be cleared, but nothing else in the specification mentions is, so it is ignored.

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**class** `pymodbus.diag_message.ClearOverrunCountResponse (data=0, **kwargs)`

Clears the overrun error counter and reset the error flag

**class** `pymodbus.diag_message.GetClearModbusPlusRequest (**kwargs)`

In addition to the Function code (08) and Subfunction code (00 15 hex) in the query, a two-byte Operation field is used to specify either a ‘Get Statistics’ or a ‘Clear Statistics’ operation. The two operations are exclusive - the ‘Get’ operation cannot clear the statistics, and the ‘Clear’ operation does not return statistics prior to clearing them. Statistics are also cleared on power-up of the slave device.

**encode ()**

Base encoder for a diagnostic response we encode the data set in self.message

**Returns** The encoded packet

**execute (\*args)**

Execute the diagnostic request on the given device

**Returns** The initialized response message

**get\_response\_pdu\_size ()**

Returns a series of 54 16-bit words (108 bytes) in the data field of the response (this function differs from the usual two-byte length of the data field). The data contains the statistics for the Modbus Plus peer processor in the slave device. Func\_code (1 byte) + Sub function code (2 byte) + Operation (2 byte) + Data (108 bytes) :return:

**class** `pymodbus.diag_message.GetClearModbusPlusResponse (data=0, **kwargs)`

Returns a series of 54 16-bit words (108 bytes) in the data field of the response (this function differs from the usual two-byte length of the data field). The data contains the statistics for the Modbus Plus peer processor in the slave device.

## device — Modbus Device Representation

### API Documentation

#### Modbus Device Controller

These are the device management handlers. They should be maintained in the server context and the various methods should be inserted in the correct locations.

**class** `pymodbus.device.ModbusAccessControl`

This is a simple implementation of a Network Management System table. Its purpose is to control access to the server (if it is used). We assume that if an entry is in the table, it is allowed accesses to resources. However, if the host does not appear in the table (all unknown hosts) its connection will simply be closed.

Since it is a singleton, only one version can possibly exist and all instances pull from here.

**\_\_contains\_\_(host)**

Check if a host is allowed to access resources

**Parameters host** – The host to check

**\_\_iter\_\_()**

Iterater over the network access table

**Returns** An iterator of the network access table

**add(host)**

Add allowed host(s) from the NMS table

**Parameters host** – The host to add

**check(host)**

Check if a host is allowed to access resources

**Parameters host** – The host to check

**remove(host)**

Remove allowed host(s) from the NMS table

**Parameters host** – The host to remove

**class pymodbus.device.ModbusPlusStatistics**

This is used to maintain the current modbus plus statistics count. As of right now this is simply a stub to complete the modbus implementation. For more information, see the modbus implementation guide page 87.

**\_\_init\_\_()**

Initialize the modbus plus statistics with the default information.

**\_\_iter\_\_()**

Iterater over the statistics

**Returns** An iterator of the modbus plus statistics

**encode()**

Returns a summary of the modbus plus statistics

**Returns** 54 16-bit words representing the status

**reset()**

This clears all of the modbus plus statistics

**summary()**

Returns a summary of the modbus plus statistics

**Returns** 54 16-bit words representing the status

**class pymodbus.device.ModbusDeviceIdentification(*info=None*)**

This is used to supply the device identification for the readDeviceIdentification function

For more information read section 6.21 of the modbus application protocol.

**\_\_getitem\_\_(key)**

Wrapper used to access the device information

**Parameters key** – The register to read

**\_\_init\_\_(*info=None*)**

Initialize the datastore with the elements you need. (note acceptable range is [0x00-0x06,0x80-0xFF] inclusive)

**Parameters** `information` – A dictionary of {int:string} of values

**\_\_iter\_\_()**

Iterater over the device information

**Returns** An iterator of the device information

**\_\_setitem\_\_(key, value)**

Wrapper used to access the device information

**Parameters**

- `key` – The register to set
- `value` – The new value for referenced register

**\_\_str\_\_()**

Build a representation of the device

**Returns** A string representation of the device

**summary()**

Return a summary of the main items

**Returns** An dictionary of the main items

**update(value)**

Update the values of this identity using another identify as the value

**Parameters** `value` – The value to copy values from

**class pymodbus.device.DeviceInformationFactory**

This is a helper factory that really just hides some of the complexity of processing the device information requests (function code 0x2b 0x0e).

**classmethod \_DeviceInformationFactory\_\_get(identity, object\_id)**

Read a single object\_id from the device information

**Parameters**

- `identity` – The identity block to pull data from
- `object_id` – The specific object id to read

**Returns** The requested data (id, length, value)

**classmethod \_DeviceInformationFactory\_\_gets(identity, object\_ids)**

Read multiple object\_ids from the device information

**Parameters**

- `identity` – The identity block to pull data from
- `object_ids` – The specific object ids to read

**Returns** The requested data (id, length, value)

**classmethod get(control, read\_code=1, object\_id=0)**

Get the requested device data from the system

**Parameters**

- `control` – The control block to pull data from
- `read_code` – The read code to process
- `object_id` – The specific object\_id to read

**Returns** The requested data (id, length, value)

**class** `pymodbus.device.ModbusControlBlock`  
This is a global singleton that controls all system information  
All activity should be logged here and all diagnostic requests should come from here.

**\_\_iter\_\_()**  
Iterates over the device counters

**Returns** An iterator of the device counters

**\_\_str\_\_()**  
Build a representation of the control block

**Returns** A string representation of the control block

**\_setDelimiter(char)**  
This changes the serial delimiter character

**Parameters** `char` – The new serial delimiter character

**\_setListenOnly(value)**  
This toggles the listen only status

**Parameters** `value` – The value to set the listen status to

**\_setMode(mode)**  
This toggles the current serial mode

**Parameters** `mode` – The data transfer method in (RTU, ASCII)

**addEvent(event)**  
Adds a new event to the event log

**Parameters** `event` – A new event to add to the log

**clearEvents()**  
Clears the current list of events

**getDiagnostic(bit)**  
This gets the value in the diagnostic register

**Parameters** `bit` – The bit to get

**Returns** The current value of the requested bit

**getDiagnosticRegister()**  
This gets the entire diagnostic register

**Returns** The diagnostic register collection

**getEvents()**  
Returns an encoded collection of the event log.

**Returns** The encoded events packet

**reset()**  
This clears all of the system counters and the diagnostic register

**setDiagnostic(mapping)**  
This sets the value in the diagnostic register

**Parameters** `mapping` – Dictionary of key:value pairs to set

## factory — Request/Response Decoders

### API Documentation

#### Modbus Request/Response Decoder Factories

The following factories make it easy to decode request/response messages. To add a new request/response pair to be decodeable by the library, simply add them to the respective function lookup table (order doesn't matter, but it does help keep things organized).

Regardless of how many functions are added to the lookup, O(1) behavior is kept as a result of a pre-computed lookup dictionary.

```
class pymodbus.factory.ServerDecoder
    Request Message Factory (Server)
```

To add more implemented functions, simply add them to the list

```
__init__()
    Initializes the client lookup tables
```

```
_helper(data)
    This factory is used to generate the correct request object from a valid request packet. This decodes from
    a list of the currently implemented request types.
```

**Parameters** `data` – The request packet to decode

**Returns** The decoded request or illegal function request object

```
decode(message)
    Wrapper to decode a request packet
```

**Parameters** `message` – The raw modbus request packet

**Returns** The decoded modbus message or None if error

```
lookupPduClass(function_code)
    Use function_code to determine the class of the PDU.
```

**Parameters** `function_code` – The function code specified in a frame.

**Returns** The class of the PDU that has a matching `function_code`.

```
class pymodbus.factory.ClientDecoder
    Response Message Factory (Client)
```

To add more implemented functions, simply add them to the list

```
__init__()
    Initializes the client lookup tables
```

```
_helper(data)
    This factory is used to generate the correct response object from a valid response packet. This decodes from
    a list of the currently implemented request types.
```

**Parameters** `data` – The response packet to decode

**Returns** The decoded request or an exception response object

```
decode(message)
    Wrapper to decode a response packet
```

**Parameters** `message` – The raw packet to decode

**Returns** The decoded modbus message or None if error

**lookupPduClass** (*function\_code*)

Use *function\_code* to determine the class of the PDU.

**Parameters** **function\_code** – The function code specified in a frame.

**Returns** The class of the PDU that has a matching *function\_code*.

## interfaces — System Interfaces

### API Documentation

#### Pymodbus Interfaces

A collection of base classes that are used throughout the pymodbus library.

**class** `pymodbus.interfaces.Singleton`

Singleton base class <http://mail.python.org/pipermail/python-list/2007-July/450681.html>

**static \_\_new\_\_** (\**args*, \*\**kwargs*)

Create a new instance

**class** `pymodbus.interfaces.IModbusDecoder`

Modbus Decoder Base Class

This interface must be implemented by a modbus message decoder factory. These factories are responsible for abstracting away converting a raw packet into a request / response message object.

**decode** (*message*)

Wrapper to decode a given packet

**Parameters** **message** – The raw modbus request packet

**Returns** The decoded modbus message or None if error

**lookupPduClass** (*function\_code*)

Use *function\_code* to determine the class of the PDU.

**Parameters** **function\_code** – The function code specified in a frame.

**Returns** The class of the PDU that has a matching *function\_code*.

**class** `pymodbus.interfaces.IModbusFramer`

A framer strategy interface. The idea is that we abstract away all the detail about how to detect if a current message frame exists, decoding it, sending it, etc so that we can plug in a new Framer object (tcp, rtu, ascii).

**addToFrame** (*message*)

Add the next message to the frame buffer

This should be used before the decoding while loop to add the received data to the buffer handle.

**Parameters** **message** – The most recent packet

**advanceFrame** ()

Skip over the current framed message This allows us to skip over the current message after we have processed it or determined that it contains an error. It also has to reset the current frame header handle

**buildPacket** (*message*)

Creates a ready to send modbus packet

The raw packet is built off of a fully populated modbus request / response message.

**Parameters** `message` – The request/response to send

**Returns** The built packet

**checkFrame()**

Check and decode the next frame

**Returns** True if we successful, False otherwise

**getFrame()**

Get the next frame from the buffer

**Returns** The frame data or “”

**isFrameReady()**

Check if we should continue decode logic

This is meant to be used in a while loop in the decoding phase to let the decoder know that there is still data in the buffer.

**Returns** True if ready, False otherwise

**populateResult(result)**

Populates the modbus result with current frame header

We basically copy the data back over from the current header to the result header. This may not be needed for serial messages.

**Parameters** `result` – The response packet

**processIncomingPacket(data, callback)**

The new packet processing pattern

This takes in a new request packet, adds it to the current packet stream, and performs framing on it. That is, checks for complete messages, and once found, will process all that exist. This handles the case when we read N + 1 or 1 / N messages at a time instead of 1.

The processed and decoded messages are pushed to the callback function to process and send.

**Parameters**

- `data` – The new packet data
- `callback` – The function to send results to

**class pymodbus.interfaces.IModbusSlaveContext**

Interface for a modbus slave data context

**Derived classes must implemented the following methods:** `reset(self)` `validate(self, fx, address, count=1)`  
`getValues(self, fx, address, count=1)` `setValues(self, fx, address, values)`

**decode(fx)**

Converts the function code to the datastore to

**Parameters** `fx` – The function we are working with

**Returns** one of [d(iscretes),i(inputs),h(oliding),c(oils)]

**getValues(fx, address, count=1)**

Validates the request to make sure it is in range

**Parameters**

- `fx` – The function we are working with
- `address` – The starting address

- **count** – The number of values to retrieve

**Returns** The requested values from a:a+c

**reset()**

Resets all the datastores to their default values

**setValues(fx, address, values)**

Sets the datastore with the supplied values

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address
- **values** – The new values to be set

**validate(fx, address, count=1)**

Validates the request to make sure it is in range

**Parameters**

- **fx** – The function we are working with
- **address** – The starting address
- **count** – The number of values to test

**Returns** True if the request is within range, False otherwise

**class pymodbus.interfaces.IPayloadBuilder**

This is an interface to a class that can build a payload for a modbus register write command. It should abstract the codec for encoding data to the required format (bcd, binary, char, etc).

**build()**

Return the payload buffer as a list

This list is two bytes per element and can thus be treated as a list of registers.

**Returns** The payload buffer as a list

## exceptions — Exceptions Used in PyModbus

### API Documentation

#### Pymodbus Exceptions

Custom exceptions to be used in the Modbus code.

**class pymodbus.exceptions.ModbusException(string)**

Base modbus exception

**\_\_init\_\_(string)**

Initialize the exception :param string: The message to append to the error

**class pymodbus.exceptions.ModbusIOException(string='')**

Error resulting from data i/o

**\_\_init\_\_(string='')**

Initialize the exception :param string: The message to append to the error

```
class pymodbus.exceptions.ParameterException(string='')
    Error resulting from invalid parameter

    __init__(string='')
        Initialize the exception

            Parameters string – The message to append to the error

class pymodbus.exceptions.NotImplementedException(string='')
    Error resulting from not implemented function

    __init__(string='')
        Initialize the exception :param string: The message to append to the error
```

## **other\_message — Other Modbus Messages**

### **API Documentation**

Diagnostic record read/write

Currently not all implemented

```
class pymodbus.other_message.ReadExceptionStatusRequest(**kwargs)
    This function code is used to read the contents of eight Exception Status outputs in a remote device. The function provides a simple method for accessing this information, because the Exception Output references are known (no output reference is needed in the function).
```

```
    __init__(**kwargs)
        Initializes a new instance

    __str__()
        Builds a representation of the request
```

**Returns** The string representation of the request

```
    decode(data)
        Decodes data part of the message.
```

**Parameters** **data** – The incoming data

```
    encode()
        Encodes the message
```

```
    execute(context=None)
        Run a read exception status request against the store
```

**Returns** The populated response

```
class pymodbus.other_message.ReadExceptionStatusResponse(status=0, **kwargs)
```

The normal response contains the status of the eight Exception Status outputs. The outputs are packed into one data byte, with one bit per output. The status of the lowest output reference is contained in the least significant bit of the byte. The contents of the eight Exception Status outputs are device specific.

```
    __init__(status=0, **kwargs)
        Initializes a new instance
```

**Parameters** **status** – The status response to report

```
    __str__()
        Builds a representation of the response
```

**Returns** The string representation of the response

**decode**(*data*)

Decodes a the response

**Parameters** **data** – The packet data to decode

**encode**()

Encodes the response

**Returns** The byte encoded message

**class** pymodbus.other\_message.**GetCommEventCounterRequest**(*\*\*kwargs*)

This function code is used to get a status word and an event count from the remote device's communication event counter.

By fetching the current count before and after a series of messages, a client can determine whether the messages were handled normally by the remote device.

The device's event counter is incremented once for each successful message completion. It is not incremented for exception responses, poll commands, or fetch event counter commands.

The event counter can be reset by means of the Diagnostics function (code 08), with a subfunction of Restart Communications Option (code 00 01) or Clear Counters and Diagnostic Register (code 00 0A).

**\_\_init\_\_**(*\*\*kwargs*)

Initializes a new instance

**\_\_str\_\_**()

Builds a representation of the request

**Returns** The string representation of the request

**decode**(*data*)

Decodes data part of the message.

**Parameters** **data** – The incoming data

**encode**()

Encodes the message

**execute**(*context=None*)

Run a read exception status request against the store

**Returns** The populated response

**class** pymodbus.other\_message.**GetCommEventCounterResponse**(*count=0, \*\*kwargs*)

The normal response contains a two-byte status word, and a two-byte event count. The status word will be all ones (FF FF hex) if a previously-issued program command is still being processed by the remote device (a busy condition exists). Otherwise, the status word will be all zeros.

**\_\_init\_\_**(*count=0, \*\*kwargs*)

Initializes a new instance

**Parameters** **count** – The current event counter value

**\_\_str\_\_**()

Builds a representation of the response

**Returns** The string representation of the response

**decode**(*data*)

Decodes a the response

**Parameters** **data** – The packet data to decode

**encode()**

Encodes the response

**Returns** The byte encoded message

**class pymodbus.other\_message.ReportSlaveIdRequest (\*\*kwargs)**

This function code is used to read the description of the type, the current status, and other information specific to a remote device.

**\_\_init\_\_(\*\*kwargs)**

Initializes a new instance

**\_\_str\_\_()**

Builds a representation of the request

**Returns** The string representation of the request

**decode(data)**

Decodes data part of the message.

**Parameters** **data** – The incoming data

**encode()**

Encodes the message

**execute(context=None)**

Run a read exception status request against the store

**Returns** The populated response

**class pymodbus.other\_message.ReportSlaveIdResponse(identifier='x00', status=True, \*\*kwargs)**

The format of a normal response is shown in the following example. The data contents are specific to each type of device.

**\_\_init\_\_(identifier='x00', status=True, \*\*kwargs)**

Initializes a new instance

**Parameters**

- **identifier** – The identifier of the slave
- **status** – The status response to report

**\_\_str\_\_()**

Builds a representation of the response

**Returns** The string representation of the response

**decode(data)**

Decodes a the response

Since the identifier is device dependent, we just return the raw value that a user can decode to whatever it should be.

**Parameters** **data** – The packet data to decode

**encode()**

Encodes the response

**Returns** The byte encoded message

## mei\_message — MEI Modbus Messages

### API Documentation

#### Encapsulated Interface (MEI) Transport Messages

```
class pymodbus.mei_message.ReadDeviceInformationRequest (read_code=None,          ob-
                                                               ject_id=0, **kwargs)
```

This function code allows reading the identification and additional information relative to the physical and functional description of a remote device, only.

The Read Device Identification interface is modeled as an address space composed of a set of addressable data elements. The data elements are called objects and an object Id identifies them.

```
__init__ (read_code=None, object_id=0, **kwargs)
```

Initializes a new instance

##### Parameters

- **read\_code** – The device information read code
- **object\_id** – The object to read from

```
__str__()
```

Builds a representation of the request

**Returns** The string representation of the request

```
decode (data)
```

Decodes data part of the message.

**Parameters** **data** – The incoming data

```
encode ()
```

Encodes the request packet

**Returns** The byte encoded packet

```
execute (context)
```

Run a read exception status request against the store

**Parameters** **context** – The datastore to request from

**Returns** The populated response

```
class pymodbus.mei_message.ReadDeviceInformationResponse (read_code=None, information=None, **kwargs)
```

```
__init__ (read_code=None, information=None, **kwargs)
```

Initializes a new instance

##### Parameters

- **read\_code** – The device information read code
- **information** – The requested information request

```
__str__()
```

Builds a representation of the response

**Returns** The string representation of the response

```
classmethod calculateRtuFrameSize (buffer)
```

Calculates the size of the message

**Parameters** `buffer` – A buffer containing the data that have been received.

**Returns** The number of bytes in the response.

`decode(data)`

Decodes a the response

**Parameters** `data` – The packet data to decode

`encode()`

Encodes the response

**Returns** The byte encoded message

## file\_message — File Modbus Messages

### API Documentation

#### File Record Read/Write Messages

Currently none of these messages are implemented

`class pymodbus.file_message.FileRecord(**kwargs)`

Represents a file record and its relevant data.

`__eq__(rlef)`

Compares the left object to the right

`__init__(**kwargs)`

Initializes a new instance

**Params** `reference_type` Defaults to 0x06 (must be)

**Params** `file_number` Indicates which file number we are reading

**Params** `record_number` Indicates which record in the file

**Params** `record_data` The actual data of the record

**Params** `record_length` The length in registers of the record

**Params** `response_length` The length in bytes of the record

`__ne__(rlef)`

Compares the left object to the right

`__repr__()`

Gives a representation of the file record

`class pymodbus.file_message.ReadFileRecordRequest(records=None, **kwargs)`

This function code is used to perform a file record read. All request data lengths are provided in terms of number of bytes and all record lengths are provided in terms of registers.

A file is an organization of records. Each file contains 10000 records, addressed 0000 to 9999 decimal or 0x0000 to 0x270f. For example, record 12 is addressed as 12. The function can read multiple groups of references. The groups can be separating (non-contiguous), but the references within each group must be sequential. Each group is defined in a separate ‘sub-request’ field that contains seven bytes:

```
The reference type: 1 byte (must be 0x06)
The file number: 2 bytes
The starting record number within the file: 2 bytes
The length of the record to be read: 2 bytes
```

The quantity of registers to be read, combined with all other fields in the expected response, must not exceed the allowable length of the MODBUS PDU: 235 bytes.

**\_\_init\_\_(records=None, \*\*kwargs)**  
Initializes a new instance

**Parameters records** – The file record requests to be read

**decode(data)**  
Decodes the incoming request

**Parameters data** – The data to decode into the address

**encode()**  
Encodes the request packet

**Returns** The byte encoded packet

**execute(context)**  
Run a read exception status request against the store

**Parameters context** – The datastore to request from

**Returns** The populated response

**class pymodbus.file\_message.ReadFileRecordResponse(records=None, \*\*kwargs)**

The normal response is a series of ‘sub-responses,’ one for each ‘sub-request.’ The byte count field is the total combined count of bytes in all ‘sub-responses.’ In addition, each ‘sub-response’ contains a field that shows its own byte count.

**\_\_init\_\_(records=None, \*\*kwargs)**  
Initializes a new instance

**Parameters records** – The requested file records

**decode(data)**  
Decodes a the response

**Parameters data** – The packet data to decode

**encode()**  
Encodes the response

**Returns** The byte encoded message

**class pymodbus.file\_message.WriteFileRecordRequest(records=None, \*\*kwargs)**

This function code is used to perform a file record write. All request data lengths are provided in terms of number of bytes and all record lengths are provided in terms of the number of 16 bit words.

**\_\_init\_\_(records=None, \*\*kwargs)**  
Initializes a new instance

**Parameters records** – The file record requests to be read

**decode(data)**  
Decodes the incoming request

**Parameters data** – The data to decode into the address

```
encode()
    Encodes the request packet

    Returns The byte encoded packet

execute(context)
    Run the write file record request against the context

    Parameters context – The datastore to request from

    Returns The populated response

class pymodbus.message.WriteFileRecordResponse(records=None, **kwargs)
    The normal response is an echo of the request.

    __init__(records=None, **kwargs)
        Initializes a new instance

        Parameters records – The file record requests to be read

    decode(data)
        Decodes the incoming request

        Parameters data – The data to decode into the address

    encode()
        Encodes the response

        Returns The byte encoded message

class pymodbus.message.ReadFifoQueueRequest(address=0, **kwargs)
    This function code allows to read the contents of a First-In-First-Out (FIFO) queue of register in a remote device. The function returns a count of the registers in the queue, followed by the queued data. Up to 32 registers can be read: the count, plus up to 31 queued data registers.

    The queue count register is returned first, followed by the queued data registers. The function reads the queue contents, but does not clear them.

    __init__(address=0, **kwargs)
        Initializes a new instance

        Parameters address – The fifo pointer address (0x0000 to 0xffff)

    decode(data)
        Decodes the incoming request

        Parameters data – The data to decode into the address

    encode()
        Encodes the request packet

        Returns The byte encoded packet

    execute(context)
        Run a read exception status request against the store

        Parameters context – The datastore to request from

        Returns The populated response

class pymodbus.message.ReadFifoQueueResponse(values=None, **kwargs)
    In a normal response, the byte count shows the quantity of bytes to follow, including the queue count bytes and value register bytes (but not including the error check field). The queue count is the quantity of data registers in the queue (not including the count register).

    If the queue count exceeds 31, an exception response is returned with an error code of 03 (Illegal Data Value).
```

---

**`__init__(values=None, **kwargs)`**  
Initializes a new instance

**Parameters** `values` – The list of values of the fifo to return

**classmethod `calculateRtuFrameSize(buffer)`**  
Calculates the size of the message

**Parameters** `buffer` – A buffer containing the data that have been received.

**Returns** The number of bytes in the response.

**`decode(data)`**  
Decodes a the response

**Parameters** `data` – The packet data to decode

**`encode()`**  
Encodes the response

**Returns** The byte encoded message

## events — Events Used in PyModbus

### API Documentation

#### Modbus Remote Events

An event byte returned by the Get Communications Event Log function can be any one of four types. The type is defined by bit 7 (the high-order bit) in each byte. It may be further defined by bit 6.

**class pymodbus.events.ModbusEvent**

**`decode(event)`**  
Decodes the event message to its status bits

**Parameters** `event` – The event to decode

**`encode()`**  
Encodes the status bits to an event message

**Returns** The encoded event message

**class pymodbus.events.RemoteReceiveEvent(\*\*kwargs)**  
Remote device MODBUS Receive Event

The remote device stores this type of event byte when a query message is received. It is stored before the remote device processes the message. This event is defined by bit 7 set to logic ‘1’. The other bits will be set to a logic ‘1’ if the corresponding condition is TRUE. The bit layout is:

Bit Contents	
<hr/>	
0	Not Used
2	Not Used
3	Not Used
4	Character Overrun
5	Currently <code>in</code> Listen Only Mode
6	Broadcast Receive
7	1

**`__init__(**kwargs)`**

Initialize a new event instance

**`decode(event)`**

Decodes the event message to its status bits

**Parameters** `event` – The event to decode

**`encode()`**

Encodes the status bits to an event message

**Returns** The encoded event message

**`class pymodbus.events.RemoteSendEvent(**kwargs)`**

Remote device MODBUS Send Event

The remote device stores this type of event byte when it finishes processing a request message. It is stored if the remote device returned a normal or exception response, or no response.

This event is defined by bit 7 set to a logic ‘0’, with bit 6 set to a ‘1’. The other bits will be set to a logic ‘1’ if the corresponding condition is TRUE. The bit layout is:

Bit Contents

0	Read Exception Sent (Exception Codes 1-3)
1	Slave Abort Exception Sent (Exception Code 4)
2	Slave Busy Exception Sent (Exception Codes 5-6)
3	Slave Program NAK Exception Sent (Exception Code 7)
4	Write Timeout Error Occurred
5	Currently in Listen Only Mode
6	1
7	0

**`__init__(**kwargs)`**

Initialize a new event instance

**`decode(event)`**

Decodes the event message to its status bits

**Parameters** `event` – The event to decode

**`encode()`**

Encodes the status bits to an event message

**Returns** The encoded event message

**`class pymodbus.events.EnteredListenModeEvent`**

Remote device Entered Listen Only Mode

The remote device stores this type of event byte when it enters the Listen Only Mode. The event is defined by a content of 04 hex.

**`decode(event)`**

Decodes the event message to its status bits

**Parameters** `event` – The event to decode

**`encode()`**

Encodes the status bits to an event message

**Returns** The encoded event message

**`class pymodbus.events.CommunicationRestartEvent`**

Remote device Initiated Communication Restart

The remote device stores this type of event byte when its communications port is restarted. The remote device can be restarted by the Diagnostics function (code 08), with sub-function Restart Communications Option (code 00 01).

That function also places the remote device into a ‘Continue on Error’ or ‘Stop on Error’ mode. If the remote device is placed into ‘Continue on Error’ mode, the event byte is added to the existing event log. If the remote device is placed into ‘Stop on Error’ mode, the byte is added to the log and the rest of the log is cleared to zeros.

The event is defined by a content of zero.

#### **decode (event)**

Decodes the event message to its status bits

**Parameters** **event** – The event to decode

#### **encode ()**

Encodes the status bits to an event message

**Returns** The encoded event message

## payload — Modbus Payload Utilities

### API Documentation

#### Modbus Payload Builders

A collection of utilities for building and decoding modbus messages payloads.

##### **class pymodbus.payload.BinaryPayloadBuilder (payload=None, endian='<')**

A utility that helps build payload messages to be written with the various modbus messages. It really is just a simple wrapper around the struct module, however it saves time looking up the format strings. What follows is a simple example:

```
builder = BinaryPayloadBuilder(endian=Endian.Little)
builder.add_8bit_uint(1)
builder.add_16bit_uint(2)
payload = builder.build()
```

##### **\_\_init\_\_ (payload=None, endian='<')**

Initialize a new instance of the payload builder

**Parameters**

- **payload** – Raw binary payload data to initialize with
- **endian** – The endianess of the payload

##### **\_\_str\_\_ ()**

Return the payload buffer as a string

**Returns** The payload buffer as a string

##### **add\_16bit\_int (value)**

Adds a 16 bit signed int to the buffer

**Parameters** **value** – The value to add to the buffer

##### **add\_16bit\_uint (value)**

Adds a 16 bit unsigned int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_32bit_float (value)`

Adds a 32 bit float to the buffer

**Parameters** `value` – The value to add to the buffer

`add_32bit_int (value)`

Adds a 32 bit signed int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_32bit_uint (value)`

Adds a 32 bit unsigned int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_64bit_float (value)`

Adds a 64 bit float(double) to the buffer

**Parameters** `value` – The value to add to the buffer

`add_64bit_int (value)`

Adds a 64 bit signed int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_64bit_uint (value)`

Adds a 64 bit unsigned int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_8bit_int (value)`

Adds a 8 bit signed int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_8bit_uint (value)`

Adds a 8 bit unsigned int to the buffer

**Parameters** `value` – The value to add to the buffer

`add_bits (values)`

Adds a collection of bits to be encoded

If these are less than a multiple of eight, they will be left padded with 0 bits to make it so.

**Parameters** `value` – The value to add to the buffer

`add_string (value)`

Adds a string to the buffer

**Parameters** `value` – The value to add to the buffer

`build()`

Return the payload buffer as a list

This list is two bytes per element and can thus be treated as a list of registers.

**Returns** The payload buffer as a list

`reset()`

Reset the payload buffer

`to_registers()`

Convert the payload buffer into a register layout that can be used as a context block.

**Returns** The register layout to use as a block

**to\_string()**

Return the payload buffer as a string

**Returns** The payload buffer as a string

**class** `pymodbus.payload.BinaryPayloadDecoder(payload, endian='<')`

A utility that helps decode payload messages from a modbus reponse message. It really is just a simple wrapper around the struct module, however it saves time looking up the format strings. What follows is a simple example:

```
decoder = BinaryPayloadDecoder(payload)
first   = decoder.decode_8bit_uint()
second  = decoder.decode_16bit_uint()
```

**\_\_init\_\_(payload, endian='<')**

Initialize a new payload decoder

**Parameters**

- **payload** – The payload to decode with
- **endian** – The endianess of the payload

**decode\_16bit\_int()**

Decodes a 16 bit signed int from the buffer

**decode\_16bit\_uint()**

Decodes a 16 bit unsigned int from the buffer

**decode\_32bit\_float()**

Decodes a 32 bit float from the buffer

**decode\_32bit\_int()**

Decodes a 32 bit signed int from the buffer

**decode\_32bit\_uint()**

Decodes a 32 bit unsigned int from the buffer

**decode\_64bit\_float()**

Decodes a 64 bit float(double) from the buffer

**decode\_64bit\_int()**

Decodes a 64 bit signed int from the buffer

**decode\_64bit\_uint()**

Decodes a 64 bit unsigned int from the buffer

**decode\_8bit\_int()**

Decodes a 8 bit signed int from the buffer

**decode\_8bit\_uint()**

Decodes a 8 bit unsigned int from the buffer

**decode\_bits()**

Decodes a byte worth of bits from the buffer

**decode\_string(size=1)**

Decodes a string from the buffer

**Parameters** `size` – The size of the string to decode

**classmethod fromCoils(klass, coils, endian='<')**

Initialize a payload decoder with the result of reading a collection of coils from a modbus device.

The coils are treated as a list of bit(boolean) values.

#### Parameters

- **coils** – The coil results to initialize with
- **Endian** – The endianess of the payload

**Returns** An initialized PayloadDecoder

**classmethod fromRegisters** (*klass, registers, endian='<'*)

Initialize a payload decoder with the result of reading a collection of registers from a modbus device.

The registers are treated as a list of 2 byte values. We have to do this because of how the data has already been decoded by the rest of the library.

#### Parameters

- **registers** – The register results to initialize with
- **Endian** – The endianess of the payload

**Returns** An initialized PayloadDecoder

**reset()**

Reset the decoder pointer back to the start

**skip\_bytes** (*nbytes*)

Skip n bytes in the buffer

**Parameters** **nbytes** – The number of bytes to skip

## pdu — Base Structures

### API Documentation

Contains base classes for modbus request/response/error packets

**class** `pymodbus.pdu.ModbusPDU(**kwargs)`

Base class for all Modbus messages

#### **transaction\_id**

This value is used to uniquely identify a request response pair. It can be implemented as a simple counter

#### **protocol\_id**

This is a constant set at 0 to indicate Modbus. It is put here for ease of expansion.

#### **unit\_id**

This is used to route the request to the correct child. In the TCP modbus, it is used for routing (or not used at all). However, for the serial versions, it is used to specify which child to perform the requests against. The value 0x00 represents the broadcast address (also 0xff).

#### **check**

This is used for LRC/CRC in the serial modbus protocols

#### **skip\_encode**

This is used when the message payload has already been encoded. Generally this will occur when the PayloadBuilder is being used to create a complicated message. By setting this to True, the request will pass the currently encoded message through instead of encoding it again.

#### **\_\_init\_\_(\*\*kwargs)**

Initializes the base data for a modbus request

---

```

classmethod calculateRtuFrameSize (buffer)
    Calculates the size of a PDU.

        Parameters buffer – A buffer containing the data that have been received.

        Returns The number of bytes in the PDU.

decode (data)
    Decodes data part of the message.

        Parameters data – is a string object

        Raises A not implemented exception

encode ()
    Encodes the message

        Raises A not implemented exception

class pymodbus.pdu.ModbusRequest (**kwargs)
    Base class for a modbus request PDU

        __init__ (**kwargs)
            Proxy to the lower level initializer

        doException (exception)
            Builds an error response based on the function

                Parameters exception – The exception to return

                Raises An exception response

class pymodbus.pdu.ModbusResponse (**kwargs)
    Base class for a modbus response PDU

        should_respond
            A flag that indicates if this response returns a result back to the client issuing the request

        _rtu_frame_size
            Indicates the size of the modbus rtu response used for calculating how much to read.

        __init__ (**kwargs)
            Proxy to the lower level initializer

class pymodbus.pdu.ModbusExceptions
    An enumeration of the valid modbus exceptions

        classmethod decode (code)
            Given an error code, translate it to a string error name.

                Parameters code – The code number to translate

class pymodbus.pdu.ExceptionResponse (function_code, exception_code=None, **kwargs)
    Base class for a modbus exception PDU

        __init__ (function_code, exception_code=None, **kwargs)
            Initializes the modbus exception response

                Parameters
                    • function_code – The function to build an exception response for
                    • exception_code – The specific modbus exception to return

        __str__ ()
            Builds a representation of an exception response

```

**Returns** The string representation of an exception response

**decode** (*data*)

Decodes a modbus exception response

**Parameters** **data** – The packet data to decode

**encode** ()

Encodes a modbus exception response

**Returns** The encoded exception packet

**class** `pymodbus.pdu.IllegalFunctionRequest` (*function\_code*, *\*\*kwargs*)

Defines the Modbus slave exception type ‘Illegal Function’ This exception code is returned if the slave:

- does **not** implement the function code **\*\*or\*\***
- **is not in** a state that allows it to process the function

**\_\_init\_\_** (*function\_code*, *\*\*kwargs*)

Initializes a IllegalFunctionRequest

**Parameters** **function\_code** – The function we are erroring on

**decode** (*data*)

This is here so this failure will run correctly

**Parameters** **data** – Not used

**execute** (*context*)

Builds an illegal function request error response

**Parameters** **context** – The current context for the message

**Returns** The error response packet

## pymodbus — Pymodbus Library

### Pymodbus: Modbus Protocol Implementation

TwistedModbus is built on top of the code developed by:

## register\_read\_message — Register Read Messages

### API Documentation

#### Register Reading Request/Response

**class** `pymodbus.register_read_message.ReadRegistersRequestBase` (*address*, *count*, *\*\*kwargs*)

Base class for reading a modbus register

---

**`__init__(address, count, **kwargs)`**  
Initializes a new instance

**Parameters**

- **address** – The address to start the read from
- **count** – The number of registers to read

**`__str__()`**  
Returns a string representation of the instance

**Returns** A string representation of the instance

**`decode(data)`**  
Decode a register request packet

**Parameters** **data** – The request to decode

**`encode()`**  
Encodes the request packet

**Returns** The encoded packet

**`get_response_pdu_size()`**  
Func\_code (1 byte) + Byte Count(1 byte) + 2 \* Quantity of Coils (n Bytes) :return:

**class pymodbus.register\_read\_message.`ReadRegistersResponseBase(values, **kwargs)`**  
Base class for responding to a modbus register read

**`__init__(values, **kwargs)`**  
Initializes a new instance

**Parameters** **values** – The values to write to

**`__str__()`**  
Returns a string representation of the instance

**Returns** A string representation of the instance

**`decode(data)`**  
Decode a register response packet

**Parameters** **data** – The request to decode

**`encode()`**  
Encodes the response packet

**Returns** The encoded packet

**`getRegister(index)`**  
Get the requested register

**Parameters** **index** – The indexed register to retrieve

**Returns** The request register

**class pymodbus.register\_read\_message.`ReadHoldingRegistersRequest(address=None, count=None, **kwargs)`**

This function code is used to read the contents of a contiguous block of holding registers in a remote device. The Request PDU specifies the starting register address and the number of registers. In the PDU Registers are addressed starting at zero. Therefore registers numbered 1-16 are addressed as 0-15.

**`__init__(address=None, count=None, **kwargs)`**  
Initializes a new instance of the request

### Parameters

- **address** – The starting address to read from
- **count** – The number of registers to read from address

**execute** (*context*)

Run a read holding request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** An initialized response, exception message otherwise

```
class pymodbus.register_read_message.ReadHoldingRegistersResponse (values=None,  
                           **kwargs)
```

This function code is used to read the contents of a contiguous block of holding registers in a remote device. The Request PDU specifies the starting register address and the number of registers. In the PDU Registers are addressed starting at zero. Therefore registers numbered 1-16 are addressed as 0-15.

**\_\_init\_\_** (*values*=None, \*\**kwargs*)

Initializes a new response instance

**Parameters** **values** – The resulting register values

```
class pymodbus.register_read_message.ReadInputRegistersRequest (address=None,  
                           count=None,  
                           **kwargs)
```

This function code is used to read from 1 to approx. 125 contiguous input registers in a remote device. The Request PDU specifies the starting register address and the number of registers. In the PDU Registers are addressed starting at zero. Therefore input registers numbered 1-16 are addressed as 0-15.

**\_\_init\_\_** (*address*=None, *count*=None, \*\**kwargs*)

Initializes a new instance of the request

### Parameters

- **address** – The starting address to read from
- **count** – The number of registers to read from address

**execute** (*context*)

Run a read input request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** An initialized response, exception message otherwise

```
class pymodbus.register_read_message.ReadInputRegistersResponse (values=None,  
                           **kwargs)
```

This function code is used to read from 1 to approx. 125 contiguous input registers in a remote device. The Request PDU specifies the starting register address and the number of registers. In the PDU Registers are addressed starting at zero. Therefore input registers numbered 1-16 are addressed as 0-15.

**\_\_init\_\_** (*values*=None, \*\**kwargs*)

Initializes a new response instance

**Parameters** **values** – The resulting register values

```
class pymodbus.register_read_message.ReadWriteMultipleRegistersRequest (**kwargs)
```

This function code performs a combination of one read operation and one write operation in a single MODBUS transaction. The write operation is performed before the read.

Holding registers are addressed starting at zero. Therefore holding registers 1-16 are addressed in the PDU as 0-15.

The request specifies the starting address and number of holding registers to be read as well as the starting address, number of holding registers, and the data to be written. The byte count specifies the number of bytes to follow in the write data field.”

**`__init__(**kwargs)`**

Initializes a new request message

**Parameters**

- **read\_address** – The address to start reading from
- **read\_count** – The number of registers to read from address
- **write\_address** – The address to start writing to
- **write\_registers** – The registers to write to the specified address

**`__str__()`**

Returns a string representation of the instance

**Returns** A string representation of the instance

**`decode(data)`**

Decode the register request packet

**Parameters** **data** – The request to decode

**`encode()`**

Encodes the request packet

**Returns** The encoded packet

**`execute(context)`**

Run a write single register request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** An initialized response, exception message otherwise

**`get_response_pdu_size()`**

Func\_code (1 byte) + Byte Count(1 byte) + 2 \* Quantity of Coils (n Bytes) :return:

```
class pymodbus.register_read_message.ReadWriteMultipleRegistersResponse(values=None,
                                                               **kwargs)
```

The normal response contains the data from the group of registers that were read. The byte count field specifies the quantity of bytes to follow in the read data field.

**`__init__(values=None, **kwargs)`**

Initializes a new instance

**Parameters** **values** – The register values to write

**`__str__()`**

Returns a string representation of the instance

**Returns** A string representation of the instance

**`decode(data)`**

Decode the register response packet

**Parameters** **data** – The response to decode

**`encode()`**

Encodes the response packet

**Returns** The encoded packet

## register\_write\_message — Register Write Messages

### API Documentation

#### Register Writing Request/Response Messages

```
class pymodbus.register_write_message.WriteSingleRegisterRequest (address=None,  
                                                               value=None,  
                                                               **kwargs)
```

This function code is used to write a single holding register in a remote device.

The Request PDU specifies the address of the register to be written. Registers are addressed starting at zero. Therefore register numbered 1 is addressed as 0.

```
__init__ (address=None, value=None, **kwargs)
```

Initializes a new instance

##### Parameters

- **address** – The address to start writing add
- **value** – The values to write

```
__str__()
```

Returns a string representation of the instance

**Returns** A string representation of the instance

```
decode (data)
```

Decode a write single register packet packet request

**Parameters** **data** – The request to decode

```
encode ()
```

Encode a write single register packet packet request

**Returns** The encoded packet

```
execute (context)
```

Run a write single register request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** An initialized response, exception message otherwise

```
get_response_pdu_size ()
```

Func\_code (1 byte) + Register Address(2 byte) + Register Value (2 bytes) :return:

```
class pymodbus.register_write_message.WriteSingleRegisterResponse (address=None,  
                                                               value=None,  
                                                               **kwargs)
```

The normal response is an echo of the request, returned after the register contents have been written.

```
__init__ (address=None, value=None, **kwargs)
```

Initializes a new instance

##### Parameters

- **address** – The address to start writing add
- **value** – The values to write

```
__str__()
```

Returns a string representation of the instance

**Returns** A string representation of the instance

**decode** (*data*)

Decode a write single register packet request

**Parameters** **data** – The request to decode

**encode** ()

Encode a write single register packet request

**Returns** The encoded packet

```
class pymodbus.register_write_message.WriteMultipleRegistersRequest (address=None,
                                                                val-
                                                                ues=None,
                                                                **kwargs)
```

This function code is used to write a block of contiguous registers (1 to approx. 120 registers) in a remote device.

The requested written values are specified in the request data field. Data is packed as two bytes per register.

**\_\_init\_\_** (*address=None*, *values=None*, *\*\*kwargs*)

Initializes a new instance

**Parameters**

- **address** – The address to start writing to
- **values** – The values to write

**\_\_str\_\_** ()

Returns a string representation of the instance

**Returns** A string representation of the instance

**decode** (*data*)

Decode a write single register packet request

**Parameters** **data** – The request to decode

**encode** ()

Encode a write single register packet request

**Returns** The encoded packet

**execute** (*context*)

Run a write single register request against a datastore

**Parameters** **context** – The datastore to request from

**Returns** An initialized response, exception message otherwise

```
class pymodbus.register_write_message.WriteMultipleRegistersResponse (address=None,
                                                                    count=None,
                                                                    **kwargs)
```

“The normal response returns the function code, starting address, and quantity of registers written.

**\_\_init\_\_** (*address=None*, *count=None*, *\*\*kwargs*)

Initializes a new instance

**Parameters**

- **address** – The address to start writing to
- **count** – The number of registers to write to

**\_\_str\_\_()**  
Returns a string representation of the instance  
**Returns** A string representation of the instance

**decode(data)**  
Decode a write single register packet packet request  
**Parameters** **data** – The request to decode

**encode()**  
Encode a write single register packet packet request  
**Returns** The encoded packet

## server.sync — Twisted Synchronous Modbus Server

### API Documentation

#### Implementation of a Threaded Modbus Server

**class** `pymodbus.server.sync.ModbusBaseRequestHandler(request, client_address, server)`  
Implements the modbus server protocol

This uses the socketserver.BaseRequestHandler to implement the client handler.

**execute(request)**  
The callback to call with the resulting message  
**Parameters** **request** – The decoded request message

**finish()**  
Callback for when a client disconnects

**handle()**  
Callback when we receive any data

**send(message)**  
Send a request (string) to the network  
**Parameters** **message** – The unencoded modbus response

**setup()**  
Callback for when a client connects

**class** `pymodbus.server.sync.ModbusSingleRequestHandler(request, client_address, server)`  
Implements the modbus server protocol

This uses the socketserver.BaseRequestHandler to implement the client handler for a single client(serial clients)

**handle()**  
Callback when we receive any data  
**send(message)**  
Send a request (string) to the network

**Parameters** **message** – The unencoded modbus response

```
class pymodbus.server.sync.ModbusConnectedRequestHandler(request, client_address,
server)
```

Implements the modbus server protocol

This uses the socketserver.BaseRequestHandler to implement the client handler for a connected protocol (TCP).

#### **handle()**

Callback when we receive any data, until self.running becomes not True. Blocks indefinitely awaiting data. If shutdown is required, then the global socket.settimeout(<seconds>) may be used, to allow timely checking of self.running. However, since this also affects socket connects, if there are outgoing socket connections used in the same program, then these will be prevented, if the specified timeout is too short. Hence, this is unreliable.

To respond to Modbus...Server.server\_close() (which clears each handler's self.running), derive from this class to provide an alternative handler that awakens from time to time when no input is available and checks self.running. Use Modbus...Server( handler=... ) keyword to supply the alternative request handler class.

#### **send(message)**

Send a request (string) to the network

**Parameters** **message** – The unencoded modbus response

```
class pymodbus.server.sync.ModbusDisconnectedRequestHandler(request, client_address,
server)
```

Implements the modbus server protocol

This uses the socketserver.BaseRequestHandler to implement the client handler for a disconnected protocol (UDP). The only difference is that we have to specify who to send the resulting packet data to.

#### **handle()**

Callback when we receive any data

#### **send(message)**

Send a request (string) to the network

**Parameters** **message** – The unencoded modbus response

```
class pymodbus.server.sync.ModbusTcpServer(context, framer=None, identity=None, address=None, handler=None, **kwargs)
```

A modbus threaded tcp socket server

We inherit and overload the socket server so that we can control the client threads as well as have a single server context instance.

#### **\_\_init\_\_(context,framer=None,identity=None,address=None,handler=None,\*\*kwargs)**

Overloaded initializer for the socket server

If the identify structure is not passed in, the ModbusControlBlock uses its own empty structure.

**Parameters**

- **context** – The ModbusServerContext datastore
- **framer** – The framer strategy to use
- **identity** – An optional identify structure
- **address** – An optional (interface, port) to bind to.
- **handler** – A handler for each client session; default is ModbusConnectedRequestHandler
- **ignore\_missing\_slaves** – True to not send errors on a request to a missing slave

**process\_request** (*request, client*)  
Callback for connecting a new client thread

**Parameters**

- **request** – The request to handle
- **client** – The address of the client

**server\_close()**  
Callback for stopping the running server

**shutdown()**  
Stops the serve\_forever loop.

Overridden to signal handlers to stop.

**class** pymodbus.server.sync.**ModbusUdpServer** (*context, framer=None, identity=None, address=None, handler=None, \*\*kwargs*)

A modbus threaded udp socket server

We inherit and overload the socket server so that we can control the client threads as well as have a single server context instance.

**\_\_init\_\_** (*context, framer=None, identity=None, address=None, handler=None, \*\*kwargs*)  
Overloaded initializer for the socket server

If the identify structure is not passed in, the ModbusControlBlock uses its own empty structure.

**Parameters**

- **context** – The ModbusServerContext datastore
- **framer** – The framer strategy to use
- **identity** – An optional identify structure
- **address** – An optional (interface, port) to bind to.
- **handler** – A handler for each client session; default is ModbusDisconnecte-dRequestHandler
- **ignore\_missing\_slaves** – True to not send errors on a request to a missing slave

**process\_request** (*request, client*)  
Callback for connecting a new client thread

**Parameters**

- **request** – The request to handle
- **client** – The address of the client

**server\_close()**  
Callback for stopping the running server

**class** pymodbus.server.sync.**ModbusSerialServer** (*context, framer=None, identity=None, \*\*kwargs*)

A modbus threaded serial socket server

We inherit and overload the socket server so that we can control the client threads as well as have a single server context instance.

**\_\_init\_\_** (*context, framer=None, identity=None, \*\*kwargs*)  
Overloaded initializer for the socket server

If the identify structure is not passed in, the ModbusControlBlock uses its own empty structure.

## Parameters

- **context** – The ModbusServerContext datastore
  - **framer** – The framer strategy to use
  - **identity** – An optional identify structure
  - **port** – The serial port to attach to
  - **stopbits** – The number of stop bits to use
  - **bytesize** – The bytesize of the serial messages
  - **parity** – Which kind of parity to use
  - **baudrate** – The baud rate to use for the serial device
  - **timeout** – The timeout to use for the serial device
  - **ignore\_missing\_slaves** – True to not send errors on a request to a missing slave

`_build_handler()`

**A helper method to create and monkeypatch** a serial handler.

**Returns** A patched handler

\_connect()

Connect to the serial server

**Returns** True if connection succeeded, False otherwise

`serve_forever()`

Callback for connecting a new client thread

## Parameters

- **request** – The request to handle
  - **client** – The address of the client

**server\_close()**

Callback for stopping the running server

```
pymodbus.server.sync.StartTcpServer(context=None, identity=None, address=None, **kwargs)
```

## A factory to start and run a tcp modbus server

## Parameters

- **context** – The ModbusServerContext datastore
  - **identity** – An optional identify structure
  - **address** – An optional (interface, port) to bind to.
  - **ignore\_missing\_slaves** – True to not send errors on a request to a missing slave

```
pymodbus.server.sync.StartUdpServer(context=None, identity=None, address=None, **kwargs)
```

## A factory to start and run a udp modbus server

## Parameters

- **context** – The ModbusServerContext datastore
  - **identity** – An optional identify structure

- **address** – An optional (interface, port) to bind to.
- **framer** – The framer to operate with (default ModbusSocketFramer)
- **ignore\_missing\_slaves** – True to not send errors on a request to a missing slave

`pymodbus.server.sync.StartSerialServer(context=None, identity=None, **kwargs)`

A factory to start and run a serial modbus server

#### Parameters

- **context** – The ModbusServerContext datastore
- **identity** – An optional identify structure
- **framer** – The framer to operate with (default ModbusAsciiFramer)
- **port** – The serial port to attach to
- **stopbits** – The number of stop bits to use
- **bytesize** – The bytesize of the serial messages
- **parity** – Which kind of parity to use
- **baudrate** – The baud rate to use for the serial device
- **timeout** – The timeout to use for the serial device
- **ignore\_missing\_slaves** – True to not send errors on a request to a missing slave

## server.async — Twisted Asynchronous Modbus Server

### API Documentation

## transaction — Transaction Controllers for Pymodbus

### API Documentation

Collection of transaction based abstractions

`class pymodbus.transaction.DictTransactionManager(client, **kwargs)`  
Implements a transaction for a manager where the results are keyed based on the supplied transaction id.

`__init__(client, **kwargs)`  
Initializes an instance of the ModbusTransactionManager

**Parameters** `client` – The client socket wrapper

`__iter__()`  
Iterates over the current managed transactions

**Returns** An iterator of the managed transactions

`addTransaction(request, tid=None)`  
Adds a transaction to the handler

This holds the requests in case it needs to be resent. After being sent, the request is removed.

**Parameters**

- `request` – The request to hold on to

- **tid** – The overloaded transaction id to use

**delTransaction (tid)**

Removes a transaction matching the referenced tid

**Parameters** **tid** – The transaction to remove

**getTransaction (tid)**

Returns a transaction matching the referenced tid

If the transaction does not exist, None is returned

**Parameters** **tid** – The transaction to retrieve

**class pymodbus.transaction.FifoTransactionManager (client, \*\*kwargs)**

Implements a transaction for a manager where the results are returned in a FIFO manner.

**\_\_init\_\_ (client, \*\*kwargs)**

Initializes an instance of the ModbusTransactionManager

**Parameters** **client** – The client socket wrapper

**\_\_iter\_\_ ()**

Iterates over the current managed transactions

**Returns** An iterator of the managed transactions

**addTransaction (request, tid=None)**

Adds a transaction to the handler

This holds the requests in case it needs to be resent. After being sent, the request is removed.

**Parameters**

- **request** – The request to hold on to
- **tid** – The overloaded transaction id to use

**delTransaction (tid)**

Removes a transaction matching the referenced tid

**Parameters** **tid** – The transaction to remove

**getTransaction (tid)**

Returns a transaction matching the referenced tid

If the transaction does not exist, None is returned

**Parameters** **tid** – The transaction to retrieve

**class pymodbus.transaction.ModbusSocketFramer (decoder)**

Modbus Socket Frame controller

Before each modbus TCP message is an MBAP header which is used as a message frame. It allows us to easily separate messages as follows:

```
[      MBAP Header      ] [ Function Code] [ Data ]
[ tid ][ pid ][ length ][ uid ]
 2b      2b      2b       1b           1b          Nb

while len(message) > 0:
    tid, pid, length, uid = struct.unpack(">HHHB", message)
    request = message[0:7 + length - 1]
    message = [7 + length - 1:]
```

```
* length = uid + function code + data
* The -1 is to account for the uid byte
```

### `__init__(decoder)`

Initializes a new instance of the framer

**Parameters** `decoder` – The decoder factory implementation to use

### `_process(callback, error=False)`

Process incoming packets irrespective error condition

### `addToFrame(message)`

Adds new packet data to the current frame buffer

**Parameters** `message` – The most recent packet

### `advanceFrame()`

Skip over the current framed message This allows us to skip over the current message after we have processed it or determined that it contains an error. It also has to reset the current frame header handle

### `buildPacket(message)`

Creates a ready to send modbus packet

**Parameters** `message` – The populated request/response to send

### `checkFrame()`

Check and decode the next frame Return true if we were successful

### `getFrame()`

Return the next frame from the buffered data

**Returns** The next full frame buffer

### `getRawFrame()`

Returns the complete buffer

### `isFrameReady()`

Check if we should continue decode logic This is meant to be used in a while loop in the decoding phase to let the decoder factory know that there is still data in the buffer.

**Returns** True if ready, False otherwise

### `populateResult(result)`

Populates the modbus result with the transport specific header information (pid, tid, uid, checksum, etc)

**Parameters** `result` – The response packet

### `processIncomingPacket(data, callback)`

The new packet processing pattern

This takes in a new request packet, adds it to the current packet stream, and performs framing on it. That is, checks for complete messages, and once found, will process all that exist. This handles the case when we read N + 1 or 1 / N messages at a time instead of 1.

The processed and decoded messages are pushed to the callback function to process and send.

**Parameters**

- `data` – The new packet data
- `callback` – The function to send results to

### `resetFrame()`

Reset the entire message frame. This allows us to skip over errors that may be in the stream. It is hard to

know if we are simply out of sync or if there is an error in the stream as we have no way to check the start or end of the message (python just doesn't have the resolution to check for millisecond delays).

```
class pymodbus.transaction.ModbusRtuFramer(decoder)
    Modbus RTU Frame controller:
```

[ Start Wait ]	[ Address ]	[ Function Code ]	[ Data ]	[ CRC ]	[ End Wait ]
3.5 chars	1b	1b	Nb	2b	3.5 chars

Wait refers to the amount of time required to transmit at least x many characters. In this case it is 3.5 characters. Also, if we receive a wait of 1.5 characters at any point, we must trigger an error message. Also, it appears as though this message is little endian. The logic is simplified as the following:

```
block-on-read:
    read until 3.5 delay
    check for errors
    decode
```

The following table is a listing of the baud wait times for the specified baud rates:

Baud	1.5c (18 bits)	3.5c (38 bits)
1200	13333.3 us	31666.7 us
4800	3333.3 us	7916.7 us
9600	1666.7 us	3958.3 us
19200	833.3 us	1979.2 us
38400	416.7 us	989.6 us

1 Byte = start + 8 bits + parity + stop = 11 bits  
(1/Baud) (bits) = delay seconds

**\_\_init\_\_(decoder)**

Initializes a new instance of the framer

**Parameters decoder** – The decoder factory implementation to use

**\_process(callback, error=False)**

Process incoming packets irrespective error condition

**addToFrame(message)**

This should be used before the decoding while loop to add the received data to the buffer handle.

**Parameters message** – The most recent packet

**advanceFrame()**

Skip over the current framed message This allows us to skip over the current message after we have processed it or determined that it contains an error. It also has to reset the current frame header handle

**buildPacket(message)**

Creates a ready to send modbus packet

**Parameters message** – The populated request/response to send

**checkFrame()**

Check if the next frame is available. Return True if we were successful.

**getFrame()**

Get the next frame from the buffer

**Returns** The frame data or “”

```
getRawFrame()
    Returns the complete buffer

isFrameReady()
    Check if we should continue decode logic This is meant to be used in a while loop in the decoding phase
    to let the decoder know that there is still data in the buffer.

    Returns True if ready, False otherwise

populateHeader()
    Try to set the headers uid, len and crc.

    This method examines self.__buffer and writes meta information into self.__header. It calculates only the
    values for headers that are not already in the dictionary.

    Beware that this method will raise an IndexError if self.__buffer is not yet long enough.

populateResult(result)
    Populates the modbus result header

    The serial packets do not have any header information that is copied.

    Parameters result – The response packet

processIncomingPacket(data, callback)
    The new packet processing pattern

    This takes in a new request packet, adds it to the current packet stream, and performs framing on it. That
    is, checks for complete messages, and once found, will process all that exist. This handles the case when
    we read N + 1 or 1 / N messages at a time instead of 1.

    The processed and decoded messages are pushed to the callback function to process and send.

    Parameters

        • data – The new packet data

        • callback – The function to send results to

resetFrame()
    Reset the entire message frame. This allows us to skip over errors that may be in the stream. It is hard to
    know if we are simply out of sync or if there is an error in the stream as we have no way to check the start
    or end of the message (python just doesn't have the resolution to check for millisecond delays).

class pymodbus.transaction.ModbusAsciiFramer(decoder)
    Modbus ASCII Frame Controller:
```

```
[ Start ][Address][ Function ][ Data ][ LRC ][ End ]
  1c          2c          2c          Nc          2c          2c

* data can be 0 - 2x252 chars
* end is '\r\n' (Carriage return line feed), however the line feed
  character can be changed via a special command
* start is ':'
```

This framer is used for serial transmission. Unlike the RTU protocol, the data in this framer is transferred in plain text ascii.

```
__init__(decoder)
    Initializes a new instance of the framer

    Parameters decoder – The decoder implementation to use
```

**addToFrame (message)**

Add the next message to the frame buffer This should be used before the decoding while loop to add the received data to the buffer handle.

**Parameters** **message** – The most recent packet

**advanceFrame ()**

Skip over the current framed message This allows us to skip over the current message after we have processed it or determined that it contains an error. It also has to reset the current frame header handle

**buildPacket (message)**

Creates a ready to send modbus packet Built off of a modbus request/response

**Parameters** **message** – The request/response to send

**Returns** The encoded packet

**checkFrame ()**

Check and decode the next frame

**Returns** True if we successful, False otherwise

**getFrame ()**

Get the next frame from the buffer

**Returns** The frame data or “”

**isFrameReady ()**

Check if we should continue decode logic This is meant to be used in a while loop in the decoding phase to let the decoder know that there is still data in the buffer.

**Returns** True if ready, False otherwise

**populateResult (result)**

Populates the modbus result header

The serial packets do not have any header information that is copied.

**Parameters** **result** – The response packet

**processIncomingPacket (data, callback)**

The new packet processing pattern

This takes in a new request packet, adds it to the current packet stream, and performs framing on it. That is, checks for complete messages, and once found, will process all that exist. This handles the case when we read N + 1 or 1 / N messages at a time instead of 1.

The processed and decoded messages are pushed to the callback function to process and send.

**Parameters**

- **data** – The new packet data
- **callback** – The function to send results to

**resetFrame ()**

Reset the entire message frame. This allows us to skip over errors that may be in the stream. It is hard to know if we are simply out of sync or if there is an error in the stream as we have no way to check the start or end of the message (python just doesn't have the resolution to check for millisecond delays).

**class pymodbus.transaction.ModbusBinaryFramer (decoder)**

Modbus Binary Frame Controller:

```
[ Start ] [Address] [ Function ] [ Data ] [ CRC ] [ End ]
 1b          1b        1b           Nb       2b      1b
* data can be 0 - 2x252 chars
* end is  '}'
* start is '{'
```

The idea here is that we implement the RTU protocol, however, instead of using timing for message delimiting, we use start and end of message characters (in this case { and }). Basically, this is a binary framer.

The only case we have to watch out for is when a message contains the { or } characters. If we encounter these characters, we simply duplicate them. Hopefully we will not encounter those characters that often and will save a little bit of bandwidth without a real-time system.

Protocol defined by jamod.sourceforge.net.

**`__init__(decoder)`**

Initializes a new instance of the framer

**Parameters** `decoder` – The decoder implementation to use

**`_preflight(data)`**

Preflight buffer test

This basically scans the buffer for start and end tags and if found, escapes them.

**Parameters** `data` – The message to escape

**Returns** the escaped packet

**`addToFrame(message)`**

Add the next message to the frame buffer This should be used before the decoding while loop to add the received data to the buffer handle.

**Parameters** `message` – The most recent packet

**`advanceFrame()`**

Skip over the current framed message This allows us to skip over the current message after we have processed it or determined that it contains an error. It also has to reset the current frame header handle

**`buildPacket(message)`**

Creates a ready to send modbus packet

**Parameters** `message` – The request/response to send

**Returns** The encoded packet

**`checkFrame()`**

Check and decode the next frame

**Returns** True if we are successful, False otherwise

**`getFrame()`**

Get the next frame from the buffer

**Returns** The frame data or “”

**`isFrameReady()`**

Check if we should continue decode logic This is meant to be used in a while loop in the decoding phase to let the decoder know that there is still data in the buffer.

**Returns** True if ready, False otherwise

**pymodbus.populateResult (result)**

Populates the modbus result header

The serial packets do not have any header information that is copied.

**Parameters** **result** – The response packet

**pymodbus.processIncomingPacket (data, callback)**

The new packet processing pattern

This takes in a new request packet, adds it to the current packet stream, and performs framing on it. That is, checks for complete messages, and once found, will process all that exist. This handles the case when we read N + 1 or 1 / N messages at a time instead of 1.

The processed and decoded messages are pushed to the callback function to process and send.

**Parameters**

- **data** – The new packet data
- **callback** – The function to send results to

**pymodbus.resetFrame ()**

Reset the entire message frame. This allows us to skip over errors that may be in the stream. It is hard to know if we are simply out of sync or if there is an error in the stream as we have no way to check the start or end of the message (python just doesn't have the resolution to check for millisecond delays).

## utilities — Extra Modbus Helpers

### API Documentation

#### Modbus Utilities

A collection of utilities for packing data, unpacking data computing checksums, and decode checksums.

**pymodbus.utilities.default (value)**

Given a python object, return the default value of that object.

**Parameters** **value** – The value to get the default of

**Returns** The default value

**pymodbus.utilities.dict\_property (store, index)**

Helper to create class properties from a dictionary. Basically this allows you to remove a lot of possible boilerplate code.

**Parameters**

- **store** – The store store to pull from
- **index** – The index into the store to close over

**Returns** An initialized property set

**pymodbus.utilities.pack\_bitstring (bits)**

Creates a string out of an array of bits

**Parameters** **bits** – A bit array

example:

```
bits    = [False, True, False, True]
result = pack_bitstring(bits)
```

`pymodbus.utilities.unpack_bitstring(string)`

Creates bit array out of a string

**Parameters** `string` – The modbus data packet to decode

example:

```
bytes  = 'bytes to decode'
result = unpack_bitstring(bytes)
```

`pymodbus.utilities.__generate_crc16_table()`

Generates a crc16 lookup table

---

**Note:** This will only be generated once

---

`pymodbus.utilities.computeCRC(data)`

Computes a crc16 on the passed in string. For modbus, this is only used on the binary serial protocols (in this case RTU).

The difference between modbus's crc16 and a normal crc16 is that modbus starts the crc value out at 0xffff.

**Parameters** `data` – The data to create a crc16 of

**Returns** The calculated CRC

`pymodbus.utilities.checkCRC(data, check)`

Checks if the data matches the passed in CRC

**Parameters**

- `data` – The data to create a crc16 of
- `check` – The CRC to validate

**Returns** True if matched, False otherwise

`pymodbus.utilities.computeLRC(data)`

Used to compute the longitudinal redundancy check against a string. This is only used on the serial ASCII modbus protocol. A full description of this implementation can be found in appendix B of the serial line modbus description.

**Parameters** `data` – The data to apply a lrc to

**Returns** The calculated LRC

`pymodbus.utilities.checkLRC(data, check)`

Checks if the passed in data matches the LRC

**Parameters**

- `data` – The data to calculate
- `check` – The LRC to validate

**Returns** True if matched, False otherwise

`pymodbus.utilities.rtuFrameSize(data, byte_count_pos)`

Calculates the size of the frame based on the byte count.

**Parameters**

- **data** – The buffer containing the frame.
- **byte\_count\_pos** – The index of the byte count in the buffer.

**Returns** The size of the frame.

The structure of frames with a byte count field is always the same:

- first, there are some header fields
- then the byte count field
- then as many data bytes as indicated by the byte count,
- finally the CRC (two bytes).

To calculate the frame size, it is therefore sufficient to extract the contents of the byte count field, add the position of this field, and finally increment the sum by three (one byte for the byte count field, two for the CRC).
